PNEUMONIA IN EARLY INFANCY AND IN CHILDHOOD

ITS MORTALITY AND TREATMENT, WITH SPECIAL REFERENCE TO THE USE OF ALCOHOL *

HENRY KOPLIK, M.D.
NEW YORK

Innumerable papers and discussions on pneumonia in infancy and childhood have been published within recent years. Most of these are based on insufficient data, as the number of cases subjected to a critical analysis are not many, and the recorded observations as to management and diagnosis do not emanate from one source. Hospital statistics, as a rule, are collated from the services of a number of attending physicians. The histories and diagnoses must, in such cases, vary widely as to points of view, and thus will militate against the reliability of the ultimate conclusions.

Many authors err primarily by assuming that the anatomic nature of pneumonia, whether bronchopneumonia or lobar pneumonia, can be determined definitely at the bedside. This is at times almost impossible, and though the age limitations of bronchopneumonia as compared with lobar pneumonia are well recognized, this is not so important to the practitioner as are other considerations that will be emphasized in this paper.

I have suggested that the study of a large series of cases of pneumonia occurring in infants and children, and extending over a considerable number of years, will give more accurate information as to frequency and mortality than the study of a limited number of cases over a period of one, two or even five years. The severity of the disease, the morbidity and the mortality, varies from year to year. In some years, the disease will be comparatively mild; in others, it will be severe. An average taken over a number of years will give more extensive and exact information as to changing modes of practice and the various forms of the disease one is likely to encounter. The fallacy of attaching undue importance to brilliant outcomes, in cases in which methods long obsolete are employed, as compared to the results in cases in which modern treatment is used, will also be shown by such a study. I need refer only to the fresh air treatment of today and to the digitalis and alcohol treatment of yesterday in order to emphasize what Niemeyer said of pneumonia years ago, namely, that the true course of pneumonia could be learned only from the cases of practitioners who, owing to their ineffective dosages of drugs, follow what practically amounts to *laissez-faire* treatment. Under normal conditions, pneumonia at any age is a self-limited disease of definite duration, and, barring complications, it has a definite tendency to recovery. If patients lose in their fight against the disease, it is because of constitutional limitations of the organism attacked and the utter inability of some patients to protect themselves against complications that exhaust their vitality and lead to fatal consequences.

The age of incidence is of the greatest importance. I have divided the first year of life into three periods, from birth to 3 months, from 3 to 6 months, and from 6 to 12 months. The age consideration is certainly more practical from a clinical standpoint than the anatomic nature of the pneumonia. A mere statistical summary of cases of bronchopneumonia throws very little light on a given case, as it does not take into sufficient account the elements of constitutional weakness in a patient and the difficulties the practitioner encounters while endeavoring by his treatment to build up a successful resistance to the disease. In some infants the pneumonia or bronchopneumonia seems to spread over the whole of both lungs. In others, the disease is sufficiently limited to justify the assumption that the inherent resistance of the organism will suffice not only to combat the disease, but also to protect itself against a spread of the lesion in the lung. This is an exceedingly important aspect of the disease, and it explains why in certain cases of young infants, no matter what is done, the disease gains headway, and the patient succumbs because of this and not through inappropriate treatment. In older children, on the other hand, the structure of the lung, as Delafield has explained, tends, in a measure, to protect the patient against a spread of the lesion. As a rule, a lobar process is limited in its attack to a definite portion of the lung, in which case patients show greater constitutional resistance to the progress of the lesion, and there is a tendency to recovery no matter what treatment is employed. If the foregoing underlying principles in regard to pneumonia in infancy and childhood are understood, all cases can be more justly analyzed and the patient may be approached with the conviction that the ultimate outcome of all pneumonia depends mainly on the vitality of the patient and his powers of resistance.

CLASSIFICATION OF CASES

It is often said that the results are far better in private than in hospital practice. If this is true, then it is an indictment against our hospital system, and is a good weapon to use against it. But it is not true; indeed, it is far from the truth. I prefer the well conducted hospital ward, free from hospitalism—its light, air, sunshine, modern methods of nursing—to the dirty, dingy, stuffy tenement, or to the harassing and annoying conditions of better private practice. The results in hospitals certainly should be as good as if not better than in private practice. I think statistics will bear me out in the statement that the clinical course of pneumonia is better in hospitals than elsewhere. The careful nursing and the freedom from noise and worry certainly tend to better results. Even the public recognizes this fact.

---

* From the pediatric service of the Mount Sinai Hospital.

The hospital physician says that if he could get the patient earlier he could do better. Most patients come to the hospital either in the beginning of the period of onset or when this period is well advanced. Some patients come in only a day before the crisis occurs, and a very few patients are brought in moribund. The argument of the hospital that the patients should be brought in earlier does not apply, therefore, to other than the moribund patients, and even as regards them, I am not convinced that bringing them to the hospital earlier would have saved them. With pneumonia it is not as with diphtheria, for in the latter early treatment saves. In pneumonia we have no specific, the early application of which would save. Therefore, our inadequate methods and not the place of treatment are to blame for our failures. Of course, some exceptions may be urged; but on analysis they will be found to be only exceptions. Very few children with pneumonia are exposed to the same dangers as some adults who walk around for days with the disease in progress, and then come to the hospital moribund. Most children are treated in their homes from the start. Their transfer to the hospital is only a change of place and cannot be used as a weapon for or against hospitals. The hospital statistics which I will present depict in a true and faithful manner the course of pneumonia in infancy and childhood. Though they are all hospital statistics, they are drawn from one service (my own), and the patients were all treated under a uniform system of therapy and nursing in a hospital of the modern type. They depict results that should obtain in private practice, and from my experience I am inclined to believe that they depict the true course of the disease under modern conditions.

I have divided my cases into two groups, Series A, comprising 1,351 cases occurring from 1906 to 1914, and Series B, in which are included all cases occurring during 1914 to 1915 and 1915 to 1916, namely, 391. The reason for this division will be given later.

I have first considered the mortality from the standpoint of age, and, in the case of infants, the incidence of fatality among the breast fed and the bottle fed, irrespective of the mode of treatment. Secondly, I have considered the influence of treatment, including nursing, and the conservation of the strength of the patient. In Series A there were 248 deaths, a mortality of 18.3 per cent. The mortality varied in different epidemics or years from 14.6 per cent. to 25.7 per cent. The percentage of mortality was increased according as the number of infants or children of younger age predominated. Comparing the mortality of the different ages in the total number of cases as shown in Table 1, it will be seen that the greatest mortality occurred below the age of 1 year and that the mortality decreased steadily after the fourth year. Thus, below 1 year of age, 334 cases showed a mortality of 35 per cent.; after the fourth year, the mortality ranged from 3.8 per cent. to 10.7 per cent., and between the seventh and eighth years, it was 3.8 per cent. These were the favorable years, when most cases were of the frank lobar type. Quite favorable was a group of cases after the tenth year, forty-six cases showing a mortality of 4.3 per cent. Omitting the first year, the record from the second to the tenth year and over was 1,017 cases, with a mortality of 131, or 12.8 per cent., certainly a very favorable showing.

All of the cases in infant[illegible]below the age of 1 year, or at least a large majority of them, are of the bronchopneumonic type. I have made an analysis of these cases to show that at this age the mortality depends on factors against which our present modes of treatment are powerless. Among these factors are the constitutional resistance of the individual and the occurrence of complications. Pneumonia finds the organism unprepared to resist either the spread of the disease or the onset of complications, which carry away the patient in spite of all we can do. Of the 117 deaths occurring below the age of 1 year, 63.5 per cent. occurred in the first three months of life, 47.8 per cent. between the ages of 3 and 6 months, and 25.3 per cent. from the sixth to the twelfth month of life. The greatest mortality occurred at a time (from birth to the third month) not only when the body is in a formative period, but also when the powers of resistance to disease are at a minimum, and when complications easily set in and overwhelm the patient. In considering the mortality in pneumonia, clinicians, as a rule, shun these cases, if they wish to show favorable results from the treatment of a number of cases of pneumonia, swamping, as it were, this high mortality rate below 1 year of age by bringing forward large numbers of cases of pneumonia at the more advanced ages of childhood, up to the second year. Or they group all the cases below 1 year of age, thus avoiding the disconcerting showing of a high mortality among infants below 3 or even 6 months of age. No one who studies the statistics here presented can find fault with the mortality of the pneumonia cases from the fourth to the tenth year; 279 cases show a mortality of only sixteen, or 5.7 per cent. This, of course, presupposes deaths in all cases not due to empyema or operation for empyema.

TABLE 1.—NUMBER OF CASES AND DEATHS ACCORDING TO AGE (SERIES A)

Age of Patient	No. of Cases	No. of Deaths	Percentage of Mortality

COMPLICATIONS

In speaking of complications, I shall consider those affecting infants and children below 2 years of age. I shall treat of their seriousness, and shall dea especially with those which in the end militate against the recovery of the patient.

Of 248 deaths below the age of 10 years, 19 patients died of or with complications. Most of the cases in patients above 2 years of age show few complications, and this incidence diminishes markedly above the third year of age. Thus, there were 117 deaths below 1 year of age, among which were ninety-three fatal cases with complications. Between the ages of 1 and 2 years the complications occurred less often, fifty-eight in eighty cases, and in the second to third year, of twenty-eight fatal cases, there were twenty-two with complications. At this later period it may safely be said that the severity of the complication as regards its hastening a fatal issue is much less than during the first year. Of 117 deaths below the age of 12 months, fully ninety-three patients had complications that favored a fatal issue. At this period of infancy a complication that in later childhood might be overcome by the patient will not yield to treatment, but steadily exhausts the strength of the patient.

Of the infants below the age of 12 months affected with pneumonia, and dying with complications, we find the incidence given in Table 5.

TABLE 3.—NUMBER OF DEATHS FROM PNEUMONIA WITH COMPLICATIONS ACCORDING TO AGE (SERIES A)

Age of Patient	Total No. of Deaths According to Age	Total No. of Deaths with Complications According to Age
1 year	117	93
1-2 years	80	58
2-3 years	28	22
3-4 years	7	6
4-5 years	6	5
5-6 years	3	2
6-7 years	4	3
7-8 years	1	1
8-9 years	0	0
9-10 years	0	0
10+ years	2	2
Total deaths		248
Total deaths with complications		192

Of the 117 cases of death occurring below 1 year of age, only nine patients came to the hospital in a moribund condition. The principal complications seemed to involve the gastro-intestinal tract. These infants were brought into the hospital in a state of marasmus, or suffering with ileocolitis. Therefore, fully half of the deaths were due to complications which lessened the chances of recovery when admitted to the hospital, and this in spite of the special nursing and care that were given them. Among the cardiac conditions were those of congenital heart lesions. In scattering cases, measles developed in the hospital, or the patients came in with measles, diphtheria, pertussis, nephritis, sepsis, abscesses of the joints and of the skin, erysipelas and tuberculosis of the abdomen. It is apparent that in the first year of life a patient with pneumonia, in order to recover, must remain free from complications, and especially must not suffer from conditions which sap the strength of the patient, and nullify all efforts of therapy. It may be said without reservation that the complications occurring in our cases were not the result of hospital conditions; that the patients were admitted to the hospital with these complications.

Meningitis.—To me the most serious complication, after that of the gastro-enteric tract, is meningitis. When accompanying a pneumonia occurring during the first year, meningitis is invariably fatal. It occurred more frequently in our statistics at this age than later in childhood. In the course of eight years, there were ten cases of meningitis at all ages verified by lumbar puncture. Five of these occurred in infants below 1 year of age. Only two cases occurred between the ages of 2 and 10 years. The frequency of this complication is thus much diminished after infancy and early childhood. The symptoms are not masked. The diagnosis of the condition is easily made. Lumbar puncture was made in all cases. Pneumococci, streptococci, meningococci and influenza bacilli were found in the puncture fluid. In the newborn the streptococci are to be sought.

Meningism.—The most misleading complication is meningism. This complication is much more frequent and misleading in older children than one would at first thought suppose. Meningism is a condition characterized by symptoms that at times closely simulate meningitis, and, as a rule, these symptoms are present from the onset of the disease. They are unconsciousness, delirium or stupor, rigidity, Kernig's sign, Brudzinski's sign, and Macewen's sign. In young infants the condition of the fontanel, whether it is bulging or not, will guide us, but in older children it is at times impossible, without lumbar puncture, to say whether or not meningitis is present. This is especially true in the onset of an apical lobar pneumonia. I have in these cases found a sterile cerebrospinal fluid, and waited patiently for three or four days before definite lung signs developed.

TABLE 4.—TOTAL NUMBER OF CASES AND DEATHS FOR EACH YEAR, ALL AGES (SERIES A)

	No. of Cases	No. of Deaths	Percentage of Mortality
1906-1907	116	27	23.2
1907-1908	157	31	19.7
1908-1909	156	23	14.6
1909-1910	177	40	22.7
1910-1911	182	33	18.1
1911-1912	210	32	15.2
1912-1913	221	28	12.6
1913-1914	132	34	25.7

In older children, as a rule, the outlook is good, though the condition of the patient may be disquieting. When these cerebral symptoms appear in younger children and infants below 2 years of age, the prognosis is grave. Thus, of sixteen patients below 2 years of age showing these symptoms, nine died, and of eight below 1 year of age, six died. Of the whole series of thirty-one cases of meningism, fifteen patients were above 2 years of age, and only three died. Above 5 years of age, none died. I would conclude, therefore, that above 5 years meningism is of no moment as clouding the eventual prognosis, but below the age of 2 years it is practically a fatal sign. In children above 5 years of age, if, after passing through pneumonia, cerebral symptoms appear just about the time one would expect improvement, the outlook is grave, especially if the local symptoms indicate no tendency to resolution.

THE BREAST FED AND THE ARTIFICIALLY FED INFANT

I have made feeding statistics of all infants below 1 year of age discharged from the hospital, and also of fatal cases for eight years, 399 cases in all. The discrepancy in figures between this and other tables is probably accounted for by the inclusion of a few cases from other services under my care. Of the 399 patients, 212 were either wholly or partly breast fed, or 53+ per cent., which is certainly an excellent showing for the mother effort. All of the infants below

6 months of age were nursed on the breast, during the illness, by the mother. In the hospital it is customary to have the mother come and nurse the baby as often as practicable. Of the 132 fatal cases below and at 1 year of age, sixty-seven patients were breast fed and sixty-five bottle fed. From this we are forced to conclude that for this class of infant the nature of the feeding was not of value as to the ultimate outcome of the case. It must not be assumed that, because an infant is breast fed, its chances of recovery are better than those of the artificially fed infant, except as shown in these statistics.

There are many so-called breast fed infants who are not robust, and to whom the breast being inadequate has not given the resistance that a successfully bottle fed infant has. I therefore would not say that, *a priori*, the nature of the feeding had any effect on the outcome, but that it was rather a question of the success of the feeding. Thus, a breast or bottle fed infant with good digestion, weight and absence of complications was better off as to prognosis than a bottle fed infant with bowel disturbance, or a breast fed infant to whom the breast has not been adequate, and in whom there were complications. Today a well fed bottle infant has as good a prognosis as the successfully fed breast infant, however heretical this statement may appear to some who believe that a breast will cover all sins of omission, as to the nutrition of the patient.

In the course of pneumonia an infant below 1 year of age, whose artificial feeding is skilfully handled and who, before the onset of the illness, has had no intestinal disturbance of moment, will combat the pneumonic process as well as the well nourished breast fed infant. In fact, the breast fed infant during pneumonia has much to contend with in the ministrations of an exceedingly nervous mother, whose breast milk seems to cause disturbance in the patient; whereas an adequately fed bottle infant has always a ration of uniform constitution, which disturbs the well-being less than the apparently more fortunate breast fed infant. Modern methods of artificial feeding of infants have not in any way compromised their resisting powers to the inroads of disease, nor can we say, as far as the prognosis is concerned, that the breast milk will succeed in cases in which the bottle fed infant may not hope to weather the storm. It is not the nature of the feeding, but rather its success in bringing a flawless constitution to the attack of pneumonia that determines the recovery or the fatal issue.

There is, of course, the reservation that among the poor and ignorant, the artificial feeding, especially in summer, is apt to cause serious and fatal gastro-enteric disturbance. At the same time, a study of the fatal cases shows that the breast alone cannot ward off a fatal issue. This is especially true in infants below 6 months, and more so below 3 months of age.

TREATMENT

The treatment of pneumonia in infants and in children may be divided into that of nursing, which includes the feeding, and the medicinal management of the case. The nursing reaches its primary importance in the period of infancy. I have pointed out how essential it is at this time to avoid mixed infections, if possible. In no field is this so evident as in the treatment of infants to the end of the eighteenth month. The care of the skin, eyes and mouth is of great and far reaching importance. Careless handling of the skin by nurses is productive of skin infections, furuncles and abscesses, which are apt to get beyond medical control and cause serious consequences. The same thing is true of other parts of the body. A nurse must, therefore, appreciate fully the necessity of cleanliness and attention to detail in order to be of the greatest aid to the physician.

This is what is meant when writers speak of hospitalism and infection. There is today no real excuse for hospitalism, and its presence should be a just cause for criticism of the efficiency of nursing and of hospitals. Very often infants who have had pneumonia are discharged from institutions in the most miserable condition. There are two sides to this picture, as far as the hospital is concerned. The patient may have come to the hospital in a worse condition than when discharged, and the attending physician may have sent the patient out believing that the convalescence would be more favored by such action, or the patient may have developed an infection in the hospital. The latter condition is inexcusable, and shows clearly that an institution which, in treating a simple condition, adds thereto that of marasmus, or vaginitis, or both, is unfit to cope in a modern way with the proper means of effecting a successful convalescence.

The feeding is a nursing as well as a medical problem in the management of pneumonia. A physician may prescribe a proper feeding, but if this feeding is not prepared and given to the patient in a proper manner, or the state of the nutritional conditions properly noted, then the physician is deprived of a powerful means to favor recovery. Not only is the nursing of these little patients important, but the nurse should be surrounded by safeguards that will aid her in her work, and she must not be hampered.

The ward should be bright and airy, with plenty of working space. The dark, damp, crowded baby ward should be a thing of the past. I have dwelt on the nursing because it is rarely spoken of in treatises or articles of the character of this one, and physicians are apt to concentrate their attention on a discussion of medical procedure, omitting what should be considered the first essential in the management of these cases.

Medical Treatment.—Any one who has seen several decades of the management of pneumonia in infants and in children must come to the conclusion that it is not the remedies that determine a successful issue, but the manner in which they are applied. Formerly, certain remedies, such as chest poultices, cold compresses around the neck, expectorants, cardiac stimulents, cardiac depressants and aconite were advocated with empiric ardor. In the treatment of pneumonia, I have been guided, first, by the proper nursing and feeding of the patients, and, then, from a medical standpoint, I have tried to support the strength of the patient with drugs, endeavoring, at the same time, to recognize complications and to meet them as quickly as I could.

Antipyretics.—I have rarely, if ever, resorted to antipyretics for the control of the fever. The fever is a valuable guide in the management of pneumonia, and it cannot be controlled to any great degree—that is, depressed—without injury to the patient. It is simply an expression of reaction of the economy against the inroads of the disease. We should allay the irritability of the nervous system and thus aid the patient to withstand the fever. It is just as well to sponge the patient with lukewarm water and not to resort to ice-cold packs, or cold baths. The ordinary application of cool water to the chest in the form of compresses is sometimes as effective as any form of hydrotherapy, provided the patient is protected from exposure when the compress is on the body, or when it is changed. If the patient is irritable, and there is a moderately severe fever curve, a warm mustard bath is effective in quieting the nervous system. After such a bath, an irritable wakeful infant will fall into a quiet sleep for hours. In short, fever is natural to pneumonia, and we should look with concern on an infant who has a low temperature curve with a severe lung lesion. There is no reaction to the infection in these cases, and it spreads. These patients are weaklings.

TABLE 6.—COMPARISON OF CASES TREATED WITH AND WITHOUT ALCOHOL (SERIES A)

With Alcohol:

	No. of Cases	No. of Deaths	Percentage of Mortality
1906-1907	116	27	23.2
1907-1908	157	31	19.7
1908-1909	156	23	14.6
1909-1910	110	29	26.3
1910-1911	13	4	30.7
1911-1912	26	8	30.7
1912-1913	34	11	32.5
1913-1914	20	11	55.0

Total number of cases treated with alcohol 632
Total number of deaths in cases treated with alcohol.. 144

Without Alcohol:

	No. of Cases	No. of Deaths	Percentage of Mortality
1906-1907	0	0	0
1907-1908	0	0	0
1908-1909	0	0	0

Total number of cases treated without alcohol 719
Total number of deaths in cases treated without alcohol.. 104
Total number of cases treated with and without alcohol.1,351
Total number of deaths in cases treated with and without alcohol 248
Average percentage of mortality 18.3

Drugs.—With infants, and even older children, we must avoid all disagreeable drug medication. I fear to "upset the stomach," as it is popularly termed, and thereby interfere with my nutritional efforts. This is of especial importance in young infants. Physicians will insist on giving calomel, ammonium carbonate, ammonium chlorid, terebene, camphor, glycyrrhiza and ipecac in large, disagreeable doses. I often ask myself, "Why?" They cause vomiting, and in some cases diarrhea, and hamper the patient to an inordinate degree. The superiority of the hypodermic method of medication is well illustrated in the management of the pneumonia of infants and young children. The stomach is left free for the assimilation of whatever food the infant may take, and the momentary pain of a hypodermic needle is more than compensated for by the freedom of the patient from dyspeptic symptoms.

Use of Alcohol.—In considering my treatment of the 1,351 cases here collated, there are two distinct periods. One period extends over the years in which alcohol in the form of whisky was freely used, and the other period comprises those cases in which no whisky was used. In this way I have been able to judge in what respect this alcoholic was of benefit to the patient. As a young physician, I saw whisky given freely to children in Bellevue Hospital, so that later as attending physician I came to favor its use for many years. In the past three years, whisky has been discarded entirely in the therapy of pneumonia. Up to 1909 all patients received more or less whisky. Then I gradually began to discard it, fearing to drop it altogether, so that, during 1911, 1912, 1913 and 1914, there was a certain proportion of cases, always increasing, in which whisky was discarded, until I finally dropped it entirely. Discarding whisky, in the case of young children in half teaspoonful and older children in teaspoonful doses, I gave exceedingly small doses of spiritus aetheris nitrosi to infants, a drop every three hours, to older children never more than 3 or 4 drops, and finally discarding this, as some infants would not take it, until from 1913 to 1914, of 132 cases of pneumonia, whisky or alcohol was used in only twenty, so that the change by which whisky was completely discarded was not made abruptly, but extended over a period of five years.

Among 632 cases of pneumonia of all ages treated by the administration of medicinal doses of whisky, there were 144 deaths, a mortality for all ages of 22.8 per cent., including the infants below 3 months and below 1 year of age. Among 719 cases treated without whisky (alcohol), there were 104 deaths, a mortality of 14 + per cent. During the years in which whisky was used in all cases, whether severe or slight, namely, the years 1906 to 1909 inclusive, there were 429 cases with eighty-one deaths, a mortality of 18 + per cent. It may be thought, and with justice, that, in the years in which alcohol was and was not used, the high mortality with alcohol might have been due to the fact that the more severe cases received the whisky; hence the higher mortality. That is only partly true; however, during the year 1912-1913, for example, of a total of 221 cases, only thirty-four were treated with alcohol; in the year 1913-1914, of 132 cases, only twenty were treated with alcohol. Thus the number treated with alcohol was steadily decreasing. We will admit for the sake of argument and conscience that only the more severe cases in late years received whisky or alcohol; hence the higher mortality. But the whisky did not enable me to save life. Therefore I discarded it.

During the years 1915 and 1916, whisky has been discarded entirely in the treatment of pneumonia and the results have been good. During 1915 and 1916 there were 391 cases. This comprises Series B of my cases, from birth to the tenth year, and above. Of these, fifty-six resulted fatally, a mortality of 14 per cent. There were 113 patients of and below 1 year of age with a mortality of thirty-three, or 29 per cent. From birth to the third month there were in these two years ten patients, practically all new-born, with septic complications, with a mortality of seven, or 70 per cent. In all these cases the pneumonia was a manifestation of general sepsis. From the third to the sixth month there were thirty-two cases, with a mortality of eight cases, or 25 per cent., and from the sixth month to the twelfth month inclusive, seventy-one cases, with a mortality of eighteen, or 25 + per cent. These figures compare not only favorably with the 1,351 cases previously cited, but give

TABLE 7.—TOTAL NUMBER OF CASES TREATED WITHOUT ALCOHOL FOR THE YEARS 1915 AND 1916 (SERIES B)

	0-3 Mos.	3-6 Mos.	6-12 Mos.	1-2 Yrs.	2-5 Yrs.	5-10 Yrs.	Totals

Total	10	32	71	113	86	79	391
Percentage of mortality	70	25	25	11	5	6	14

no support whatever for the alcohol treatment of former years, especially if we look at the percentage mortality: from the first to the second year, 113 cases with a case mortality of thirteen, or 11 per cent.; from the second to the fifth year, eighty-six cases with a case mortality of five, or 5 per cent.; from the fifth to the tenth year, seventy-nine cases, with a case mortality of five, or 6 per cent. These statistics prove beyond any doubt not only all the data as to the high mortality in the new-born period, but the benign nature of pneumonia in later childhood under careful nursing, and hold out no encouragement for the older methods of active alcoholic administration. The use of whisky in former years was not justified by the results attained. The complete disuse of alcohol has not harmed my patients.

Cold Air; Fresh Air.—In the treatment of pneumonia the rôle of cold fresh air has been exploited though there were something in the freezing air at would act as a specific in bringing about a favorable result. I found by careful study that both infants and young children stand cold very badly. Some patients seem to struggle against its effect, instead of accepting the cold as a relief from their sufferings. Some infants, when placed warmly bundled up in a cold room with open windows, grow cyanosed, and the whole system seems depressed. Rarely will an infant placed in the cool, open room react in a manner to make us feel that we are helping the patient. The pale infant becomes blue, the ruddy infant, pale. I have finally concluded that the middle course of giving fresh air which, if possible, is at a temperature that is not uncomfortable to the nurse, is the correct procedure. If we can place the patient in a room in which the incoming air passes over a warm radiator, it is probably the ideal condition. The air in the sick room should be fresh and crisp, but not icy cold. Cold is not specific in the treatment of pneumonia; certainly not cold air.

Hypodermic Medication.—Wherever it is possible, I set great store by the hypodermic method of medication, properly carried out by a careful nurse, avoiding skin infections. The use of camphor (which is not at all new) suspended in oil, with or without caffein, has proved the most satisfactory from a clinical standpoint. Camphor is a mild cardiac stimulant. After its injection I have found the pulse stronger and more forceful, but only for a short time. I regard it, like all the resins and balsams, as a mild expectorant, so that its use is justified in two directions. I have never seen any harm result to the kidney from proper dosage. It is difficult to lay down the exact dosage, but camphor suspended in oil may be given subcutaneously at three hour intervals, a grain for every year of the age, up to 3 or 4 grains. It may be given to the new-born in doses from one-fourth to one-half grain. Caffein is also a useful remedy. It is one of our best cardiac stimulants, but we must remember that it has been shown to be, in large doses, a poison. Therefore caution must be exercised in its use.

Digitalis has lately been brought into notice in the treatment of pneumonia. Given in adequate doses it is useful. The tincture may be used in therapeutically effective doses, but in cases in which a tachycardia develops with threatened breakdown of the heart with enlargement of the liver, the tincture is of little avail. In these cases digipuratum, given intravenously in full dosage twice in twenty-four hours, is of great efficacy. It is the only agent that will avert a cardiac collapse.

SUMMARY

It is evident that I regard the treatment of pneumonia at the present day as symptomatic, and that I believe pneumonia to be a disease in which clinical experience must go hand in hand with good judgment, in order that the patient may not be injured while making the fight for recovery. As to serums or vaccines, they have been even less successful in the final results in children than in adults. Their use is still in a developmental stage.

TOXIC FACTORS OF SOME OF THE COMMON ANESTHETIC SUBSTANCES *

EVARTS A. GRAHAM, M.D.
MASON CITY, IOWA

Much of the popular dread of an operation is based on fear of the anesthesia. The laity regards the possibility of a failure to regain consciousness as the chief hazard of most operations. This fear, of course, is traditional from the time when it was not infrequent for patients to die from a badly conducted anesthesia, while the operation was in progress. Surgeons also, even up to very recent times, felt that about the only danger from a narcosis was that of immediate death. The recognition of the condition of so-called "late chloroform poisoning" performed the very important function not only of awakening surgeons to the fact that death from chloroform may occur two or three days after its administration, but also of calling attention to a large number of toxic effects directly ascribable to the induction of general anesthesia, no matter by what anesthetic drug. Many of the unexpected, disastrous results following apparently simple operative procedures are more or less directly the result of the narcosis, even though these results may not be immediately apparent. A consideration of the possible toxic factors of the anesthetic agents, therefore, is highly important in serving to prepare the way for the avoidance of many of these disasters, and in insuring a greater margin of safety to the patient who undergoes an operation.

The phenomenon of narcosis is always accompanied by a condition of diminished oxidations. It therefore always indicates a condition of more or less severe asphyxia of the tissues, even if the frequency and depth of the respirations of the narcotized subject are normal. This has been abundantly shown by the work of Verworn,[1] Mathews,[2] Tashiro[3] and others. Verworn has even concluded, although probably incorrectly, that the phenomenon of narcosis is the same as cellular asphyxia. In 1912[4] I called attention to the close similarity which exists between the lesions of so-called late chloroform poisoning and those which can be induced by direct asphyxia. J. Loeb[5] has shown that an asphyxiated tissue always becomes acid. It is not surprising, therefore, that every surgical anesthesia induces many of the signs of an acid intoxication. As is well known, also, an existing acidosis is always aggravated by a surgical anesthesia.

---

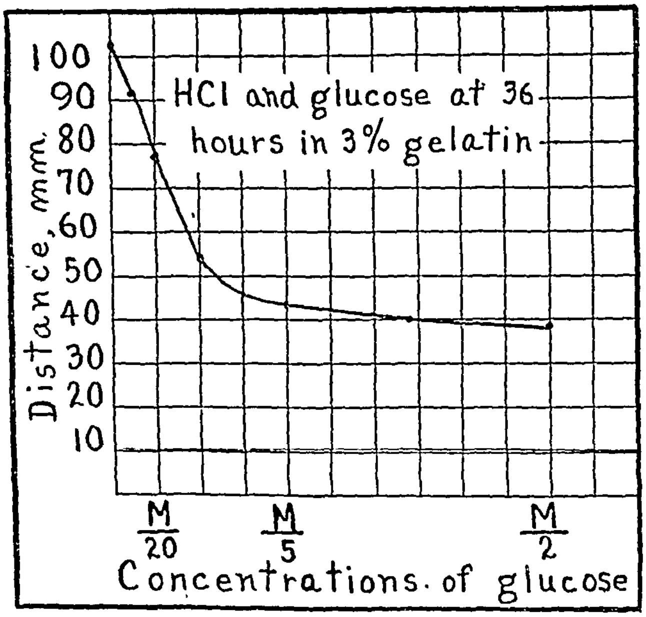
The power of the various common anesthetic substances to induce severe toxic effects varies greatly. For example, ether and nitrous oxid cause these changes much less readily than does chloroform; and nitrous oxid has only slight tendency to induce them. The explanation of the increased toxicity of chloroform over ether and nitrous oxid is probably to be found in the fact that during the breakdown of chloroform in the body hydrochloric acid is formed. Neither nitrous oxid nor ether can yield a strong mineral acid in their breakdown. Therefore, chloroform, in addition to giving rise to an acidosis as a result of the narcosis asphyxia, actually yields a strong inorganic acid as well. The morphologic changes in the tissues characteristic of late chloroform poisoning, such as edema, hemorrhages, fatty changes and central necrosis of the liver, are probably really the effects of hydrochloric acid. I have given elsewhere evidence in support of this view,[6] which evidence may be thus epitomized:

1. It is well known that, in the test tube, chloroform, in the presence of oxygen and water, is readily decomposed into hydrochloric acid. This decomposition is expressed in the following equations:

$$CHCl_3+O \rightleftarrows COCl_2+HCl$$
$$COCl_2+H_2O \rightleftarrows CO_2+2HCl$$

It is reasonable to suppose, therefore, that in the tissues where available oxygen and water are at hand, each molecule of chloroform might yield three molecules of hydrochloric acid, if the decomposition were complete. That such a decomposition actually does occur in the body seems to be apparent from the following facts obtained in a study of the condition of so-called late chloroform poisoning.



Curve showing the inhibition of diffusion of hydrochloric acid in gelatin by various concentrations of glucose. It is noticed that the smaller concentrations induce relatively the greater inhibition. The tubes were kept at a constant temperature of 26 C.

2. Hydrochloric acid in suitable concentrations induces experimentally a picture similar to that of delayed chloroform poisoning. In dogs intraportal injections of from 10 to 25 c.c. of from one-seventh to two-sevenths normal concentrations of hydrochloric acid results in the development of changes in the liver which closely parallel those obtained with chloroform, such as necrosis, fatty changes, hemorrhages and edema.

3. Attempts to recognize the presence of free hydrochloric acid in the surviving livers of animals, in which the condition of late chloroform poisoning had been experimentally produced, resulted in a demonstration, by means of neutral red, of free hydrogen ion, and, by means of silver nitrate, of an excess of free chlorin ion. For various reasons, however, this finding cannot be taken as proof of the presence of free hydrochloric acid. It is merely an indication.

4. Since chloroform is the trichlorin substitution product of methane, and since the other chlorin substitution products can yield, outside of the body at least, the same number of molecules of hydrochloric acid that there are atoms of chlorin in their respective molecules, it seemed of interest to study some of these other products in relation to their respective ability to induce the lesions of chloroform poisoning. Theoretically, we should expect the series to run in this order on the basis of their respective powers to induce these changes:

$$CH_3Cl<CH_2Cl_2<CHCl_3<CCl_4$$

Only the last three substances were used to test this point. The accompanying table shows that the toxicity, or the ability of these substances to induce the lesions in question, is roughly proportional to the number of molecules of hydrochloric acid which they can yield in their breakdown outside the body. The theory, therefore, is shown to hold.

5. Alkali, when given to dogs in suitable concentrations simultaneously with chloroform, inhibits to a marked degree the production of the typical lesions by chloroform. This fact alone, of course, lends strong support to the idea that these lesions are effects of an acid intoxication.

6. Iodoform (CHI_3) and bromoform ($CHBr_3$), which are similar in structure to chloroform ($CHCl_3$), likewise produce lesions which are indistinguishable from those of chloroform. In their cases, however, we should expect to be dealing with hydriodic and hydrobromic acids, respectively, instead of hydrochloric. As a matter of fact, positive evidence is present that after the administration of these substances these acids are actually formed in the body, for their neutral salts are found in large quantities in the urine, just as after the administration of chloroform an excess of chlorids is present in the urine.

RELATIVE TOXICITY OF SUBSTANCES

Substance	Minimal Fatal Doses per Kilogram of Rabbit Gm.	Minimal Fatal Doses Expressed in Grammolecular Concentrations
CCl_4	0.053	0.000344
$CHCl_3$	0.085	0.000711
CH_2Cl_2	0.147	0.001610

7. Strong evidence is also at hand to show, as would be expected, that the halogen substitution products of ethane act in a similar manner to those of methane both in producing the same type of lesions and in yielding their respective halogen acids, hydrochloric, hydrobromic and hydriodic acids, in their breakdowns

---

[6] Graham, E. A.: Late Poisoning with Chloroform and Other Alkyl Halides in Relationship to the Halogen Acids formed by their Chemical Dissociation, Jour. Exper. Med., 1915, **22**, 48.

in the body. The substances used to determine this fact were: ethyl chlorid (C_2H_5Cl), ethyl bromid (C_2H_5Br), ethyl iodid (C_2H_5I), and ethylene bromid ($C_2H_4Br_2$).

8. That the poisonous effects of chloroform are due rather to the hydrochloric acid which it yields than to the mere presence in its molecule of three atoms of chlorin is shown by the fact that chloral hydrate $(CCl_3{-}CH\begin{smallmatrix}/OH\\ \backslash OH\end{smallmatrix})$, which also possesses three atoms of chlorin, is incapable of producing the lesions typical of chloroform poisoning. This substance is excreted from the body as trichlor-ethyl-glycuronic acid and is therefore incapable of forming appreciable amounts of hydrochloric acid in the body.

It is an interesting and well known fact that an organ which is richly supplied with glycogen is much less susceptible to the action of various poisons. This protective action of glycogen has frequently been shown in connection with those intoxications which are associated with an acidosis. In a previous article[7] I have shown that the remarkable resistance of young pups to the production of late chloroform poisoning is due to the high glycogen content of their livers. The question of how glycogen protects against these various poisons has never been satisfactorily answered. In an attempt to study this question, and on the basis of a brief observation by Bechhold and Ziegler,[8] I have been able to show[9] that glucose markedly inhibits the diffusion of acids through gels. Since, in the presence of an acid, glycogen is readily depolymerized into glucose, it is probable that, in the case of acid poisons, the protective action of glycogen is really carried out by glucose. It is therefore probable that this property which glucose possesses of inhibiting the diffusion of acids through gels is at least somewhat concerned in the protection of the cell or certain phases of the cell against acid poisons (see chart).

Up to this point only those toxic factors of anesthetics have been discussed which deal with the formation of acids within the body. There are many other factors which doubtless are of importance, some of which, like acetone for example, are formed secondarily and probably as a result of the inhibition of oxidations during the course of the narcosis. But besides these, we must consider certain points which are concerned with the fundamental chemistry of the substances which induce anesthesia, and which may be more or less intimately related to the whole problem of the nature of the state of anesthesia itself. I refer now to the dissociation products of these substances other than acids. Limitations of time will not allow more than a mere indication of these.

For a number of years before his death, J. U. Nef[10] had been accumulating a mass of evidence to show that many carbon compounds owe their reactivity to a dissociation of such a type that a product containing unsaturated carbon is formed. The tremendous reactivity, and therefore probably the toxicity of the cyanids is probably due to the fact that cyanid with unsaturated or bivalent carbon is always present in any cyanid solution together with that which is saturated and inactive. This may be shown as follows:

$$K{-}C{\equiv}N \rightleftarrows K{-}N{=}C\rightrightarrows$$

Likewise alcohol, ether, the alkylhalids, and other substances, probably dissociate in such a way as to yield bivalent carbon, thus:

CH_3CH_2OH	$\rightleftarrows$	$CH_3CH\rightrightarrows$	$+$	HOH[11]
Alcohol (ethyl)		Alkylidene (Unsaturated carbon component)		wafer
$(CH_3CH_2)_2O$	$\rightleftarrows$	$2CH_3CH\rightrightarrows$	$+$	HOH
Ether (ethyl)		Two alkylidene		Water
CH_3CH_2Cl	$\rightleftarrows$	$CH_3CH\rightrightarrows$	$+$	HCl
Ethyl chlorid		Alkylidene		Hydrogen chlorid
Cl_3HC	$\rightleftarrows$	$Cl_2\rightrightarrows$	$+$	HCl
Chloroform (trichlormethane)		Alkylidene		Hydrogen chlorid

It has long been considered that carbon monoxid likewise owes many of its properties to its unsaturated carbon $O{=}C\rightrightarrows$

Since both the cyanids and carbon monoxid produce effects on the body similar to those of the common anesthetic substances, it is very interesting that probably they all are capable outside of the body of dissociating in a similar manner to yield an unsaturated carbon residue. That this type of dissociation also occurs within the body, at least in the case of the alkylhalids, seems to be indicated in the work described above, which shows that hydrochloric acid is formed within the body during the breakdown of chloroform, hydrobromic acid during the breakdown of bromoform, etc. It is therefore highly probable that, in a manner analogous to the case of the cyanids and carbon monoxid, the toxic properties of many of the anesthetic substances are partly due to the unsaturated carbon residue.

SUMMARY

The common anesthetic substances yield toxic products indirectly by the formation of various asphyxial acids and by favoring the formation and accumulation of many toxic products of metabolism other than acids.

Certain anesthetic substances, notably those which belong to the group of alkylhalids, in addition, are capable of yielding strong mineral acids in the tissues as dissociation products. For example, chloroform is broken down in such a way as to yield hydrochloric acid in the body.

The common anesthetic substances are capable of dissociating in a manner which yields bivalent, or unsaturated, carbon. The toxicity of the cyanids and carbon monoxid probably depends largely on their property of dissociating in a similar manner. It is therefore probable that some of the effects of the anesthetic substances are due to their unsaturated residues.

ABSTRACT OF DISCUSSION

Dr. C. Henry Davis, Chicago: I have been particularly interested in the study of chloroform, ether and nitrous oxid-oxygen as regards their relative toxicity during pregnancy and labor. Using a specially constructed chamber, these anesthetics were administered to groups of pregnant and nonpregnant guinea-pigs under very similar conditions and the results correlated with clinical observations. Two of the four guinea-pigs subjected to six hours of chloroform anesthesia died in convulsions and showed the typical central necrosis of the liver, such as has been described. Young guinea-pigs, born after the mothers had one hour of chloroform-oxygen anesthesia, had very fatty livers. Oxygen may lessen the danger of chloroform to the mothers, since the respiration is always much slower and more shallow than when ether or nitrous oxid-oxygen is administered.

[11] The sign $\rightleftarrows$ in these formulas is equivalent to "is in equilibrium with." The sign $\rightrightarrows$ signifies "free" bonds or valences; in other words the carbon atom to which they are attached is what Nef termed "bivalent carbon."

Ether and nitrous oxid-oxygen never produce tissue changes such as we have shown in chloroform poisoning. They do interfere with cell metabolism, and when given over long periods produce changes which are of the type found after simple asphyxiation. Dr. Graham has given us a very clear and logical explanation for this difference in toxicity of the various anesthetics.

CHRONIC DIARRHEAS DUE TO ENTEROCOLONIC CONDITIONS *

JULIUS FRIEDENWALD, M.D.
Professor of Gastro-Enterology, University of Maryland School of Medicine and the College of Physicians and Surgeons
BALTIMORE

It is a rather difficult task to arrange a satisfactory classification of the different varieties of chronic diarrheas due to enterocolonic conditions. This is largely due to the fact that with improved methods of investigation the etiology of hitherto undetermined forms is gradually being made clear, necessitating frequent changes in classification. Since the term "diarrhea" is used only for a symptom denoting the passage of liquid feces, it not only embodies those forms due to disease of the gastro-intestinal tract, but it is also indicative of those varieties due to conditions arising outside of this tract, such as one commonly observes in toxic states, as is seen, for instance, in nephritis or in the disturbances of internal secretion.

I have followed the accompanying classification in the study of my cases, although I recognize fully its incompleteness:

1. Simple catarrhal enterocolitis.
2. Ulcerative colitis:
   (*a*) Amebic.
   (*b*) Bacillary.
   (*c*) Tuberculous.
   (*d*) Syphilitic.
   (*e*) Carcinomatous.
3. Mucous colitis.
4. Simple colonic infections.
5. Intestinal stasis.
6. Chronic appendicitis.
7. Disturbances of the glands of internal secretion:
   (*a*) Pancreas.
   (*b*) Suprarenal.
   (*c*) Thyroid.
8. Diarrheas of toxic and undetermined origin.

It is sometimes important to differentiate a diarrhea originating from disease of the large bowel from that of the small bowel. This is especially important when surgical interference is contemplated.

In catarrh of the small bowel, the diarrhea is less intense and the pains are colicky in character. The feces are more acid, and contain unchanged bile and undigested food particles.

Mucus is frequently absent, or is present in small amount, and then admixed with the stool. In those instances in which the diarrhea originates in the large bowel, the pain is usually associated with marked tenesmus, and is less frequent than in catarrh of the small bowel. The tenderness on pressure is usually felt along the course of the colon, and not in the umbilical region. Gastric disturbances are usually absent in this affection, and the stools rarely contain undigested food. They are ordinarily alkaline and contain mucus and altered bile.

In this study of my cases of chronic diarrheas I have selected 100 cases, and these have been most carefully investigated. Thirteen cases represent those forms due to achylia gastrica, which cannot be considered here, while thirty-one represent the variety known as catarrhal colitis.

SIMPLE CATARRHAL ENTEROCOLITIS

In all of these cases there was a persistent diarrhea extending over several years, with frequent acute attacks associated with pain and tenderness over the colon; in every instance there was considerable mucus in the stools, together with blood at times. I am firmly of the opinion that the presence of mucus alone in the stools is not sufficient to warrant a diagnosis of catarrhal enterocolitis without the presence of the other symptoms already mentioned. In this disorder the characteristic appearance is usually presented by proctoscopic examination.

It was interesting to note the nature of the gastric secretion in these cases of chronic catarrhal colitis. In eighteen, the gastric secretion was quite normal; there was a hyperacidity in six, and seven presented an achylia gastrica. It is important in all cases of diarrhea associated with an achylia gastrica to determine whether or not the bowel is likewise affected, since in these instances treatment of the gastric disease alone is not sufficient to effect a cure. In the study of our cases of catarrhal colitis, the Schmidt test diet has been of considerable value. On this diet the stool is observed to be liquid or semisolid; rather large, and somewhat brown or light in color, containing more or less mucus in large or small flakes. It has a very fermented odor and contains many gas bubbles. To the naked eye there are no undigested meat fibers, and no excess of fat is present. Microscopically nothing of consequence is noted. The specimen is usually alkaline, and the sublimate test presents a normal coloration. When the stool is placed in the incubator, more or less gas is generated, indicating slight decomposition or putrefaction. Examination for dissolved protein is lightly or markedly positive.

The treatment of the various forms of catarrhal colitis is usually satisfactory. Diet plays an important rôle in this direction. In addition, most of these patients do best when treated with irrigations. Of these, solutions of potassium permanganate, boric acid, gelatin or instillations of protargol are most valuable. The internal administration of large doses of tannigen or bismuth subcarbonate is helpful.

AMEBIC DYSENTERY

Of the ulcerative forms of colitis, the amebic occurred in eight cases in this series. Since this is not an infrequent form of dysentery, the ameba should be looked for in all cases of chronic dysentery. These organisms are best observed in the scrapings obtained from the ulcerations through the proctoscope. The treatment with quinin irrigations and the administration of emetin need scarcely be mentioned here.

According to Nixon, the use of chaparro amargosa is valuable as a substitute for emetin in this disease. Cases that have resisted the emetin treatment have been controlled, according to him, by means of this drug. The plant is a small thorny bush indigenous to Texas and in Mexico. Nixon employs the drug as an infusion in doses of from 6 to 8 ounces.

---

* Read before the Section on Gastro-Enterology and Proctology at the Sixty-Eighth Annual Session of the American Medical Association, New York, June, 1917.

BACILLARY DYSENTERY

There was present in our series but one case of bacillary dysentery. The diagnosis of this condition is usually difficult. The *Bacillus dysenteriae* may occasionally be found in the stools, and when obtained will agglutinate with the blood serum. Whenever amebas cannot be discovered in the stools, this condition must be suspected, and attempts should be made to isolate the organism. According to Shiga this disorder is only a subsequent disease in which it is impossible often to isolate the dysenteric bacillus. In this condition the feces are found mixed with mucus and the débris from the ulcerated areas. Most frequently, however, the mucus is simply hanging to the feces, not being intimately mixed with it. The result of treatment of these cases is not always gratifying. In addition to diet and rest, the best results are obtained by means of irrigations. Of the remedies to be utilized for this purpose, silver nitrate solution (1:500 or 1:1,000), potassium permanganate and tannin are probably the best. Internal medication is usually of little value. Of the remedies that may be employed, bismuth is of some value. In many of these cases, occasional mild purges are sometimes helpful. Of these, castor oil or liquid petrolatum oil is the best.

TUBERCULOUS ULCERATIONS

Tuberculous ulcerations occurred in four instances in our series. These are exceedingly frequent complications of chronic pulmonary tuberculosis and especially frequent as a late manifestation of this disease. This condition is not always associated with a persistent diarrhea, and alternating constipation and diarrhea is not infrequent. Diarrhea is more pronounced when the lesions are in the lower bowel. Pain is the most frequent symptom, occurring usually in the lower abdomen, and it is often most severe before the passage of a stool or after taking food. The stools may be very frequent, and at times may contain small quantities of blood. It is unusual, however, to note the passage of large quantities of blood. Mucus in variable quantities is often admixed with the feces. The finding of tubercle bacilli in the stools is of little diagnostic value, for these organisms are frequently present in patients affected with pulmonary tuberculosis having these organisms in the sputum. Of great interest are those cases of localized tuberculosis occurring about the ileocecal region.

In this condition a definite mass is found frequently resembling a malignant growth. In these cases, in addition to the paroxysmal pains, diarrhea alternating with constipation is observed. In two cases of this variety an operation was performed by Dr. Finney for me with most gratifying results. The treatment of the diarrhea observed in intestinal tuberculosis is exceedingly difficult. Diet and rest play a most important rôle in this direction. Physiologic sodium chlorid irrigations may at times be beneficial, but sooner or later it becomes necessary to administer opium by mouth or by bowel.

SYPHILITIC ULCERATIONS

Syphilitic ulcerations of the small intestines are rarely observed. The most common lesion of this disease is in the rectum. This occurred in two of the cases in my series. When the affection involves the small intestine, the symptoms are those of an ordinary intestinal ulceration, that is, persistent and painful diarrhea remaining unrelieved by the ordinary treatment. When involving the rectum, the picture is so characteristic as to render the diagnosis exceedingly simple. The indurated edges of the elevated ulcer with the smooth base, together with gradually increasing stenosis, is ordinarily sufficiently characteristic to permit of a definite diagnosis.

CARCINOMATOUS ULCERATIONS

This condition occurred in two cases of my series. Carcinoma of the intestine more frequently occurs in the colon and in the rectum, though the disease may occur in the duodenum, jejunum and ileum. Symptoms of obstruction are among the early signs of this affection. These are manifested by attacks of colic associated with constipation. As the disease advances, the contracted area sometimes ulcerates, and constipation may give rise to a marked diarrhea with mucopus and blood in the stools. Of interest in this connection is carcinoma of the pancreas, which is frequently accompanied by a special train of symptoms pointing directly to the affection. In the earlier stages of this disease, the symptoms referable to disorder of the gastro-intestinal tract are manifested. These are especially loss of appetite, nausea and vomiting. There is usually constipation, which is rapidly transformed into diarrhea. The diarrhea becomes more and more intense, and at times fatty stools are observed. After a longer or shorter period of time jaundice appears, which gradually becomes more and more pronounced. The urine at times contains sugar; the liver enlarges and becomes nodulated, and further evidences of malignancy are noted by the cachexia. This affection is of such frequent occurrence that whenever a persistent diarrhea is observed in persons over 40 years of age which cannot be accounted for by the usual causes, carcinoma of the pancreas should be borne in mind.

MUCOUS COLITIS

Mucous colitis is such a well known affection that but little new can be said concerning it. There are three theories regarding the etiology of this affection: first, that it is entirely a nervous affection and that the mucus formed is purely a nervous hypersecretion; second, that it is due to a catarrh of the bowel, and thus has invariably an anatomic basis, and third, that the disease is due both to a nervous irritation and to a catarrhal condition.

Mucous colitis is always associated with evidences of disturbance of the autonomic nervous system, and there are present the signs of a vagotonia. While constipation is usually a prominent symptom, diarrhea is occasionally observed in this disease. This affection occurred in nine cases of our series. In addition to the usual treatment of this disorder, I should like to direct attention to the use of autogenous vaccines, which may be of great benefit in some instances.

COLONIC INFECTION

Among the infections of the bowel that may give rise to persistent diarrhea (not including the amebic and bacillary forms already referred to) there are various other micro-organisms and parasites that may play an important rôle in this connection. Of these may be mentioned certain intestinal worms, including tapeworms, whipworms, flukeworms, strongyloides and various flagellate parasites. The diagnosis of any of these conditions can be readily made by a careful examination of the stools. These infections occurred in six cases of my series.

INTESTINAL STASIS

There are three well marked varieties of intestinal stasis that may give rise to persistent diarrhea. In the first form, the stasis is due to a dilated cecum in connection often with a dilated colon, which is frequently prolapsed and which retains its contents for an unusually long period of time. On account of the retention, fermentation is produced, which is followed by diarrhea. In the second form, on account of the prolonged retention, the fecal masses are channeled, through which the stools pass in a diarrheal form. In the third form, the diarrhea is due to a spastic condition of the bowel giving rise to a frequent expulsion of small round scybala.

The lower bowel is constantly filled with these masses, which produce an irritability of the bowel and frequent desire for defecation. In all of these forms, roentgen-ray and proctoscopic examinations will quickly clear up the diagnosis. Intestinal stasis as a cause of diarrhea occurred in eight cases of my series.

CHRONIC APPENDICITIS

Although diarrhea is rarely observed as a symptom of chronic appendicitis, I am convinced that appendicitis occasionally gives rise to this symptom notwithstanding the fact that these forms of diarrheas are usually attributed to other disturbances, such as colitis or disease of the cecum. This condition occurs most frequently when the inflamed appendix is plastered against the bowel. In one of my cases the nature of the trouble was revealed by the roentgen ray. There were no symptoms definitely relating to the appendicitis, except the diarrhea. In the other case, the patient developed an acute attack of appendicitis. The appendix was removed, and there were no further symptoms. There were three cases of this affection in my series.

DISTURBANCES OF THE GLANDS OF INTERNAL SECRETION

The diarrhea accompanying the disorders of internal secretion need be considered here only so far as these may provoke changes in the intestinal mucosa, on account of which fermentation and diarrhea may be produced.

In the thyroid forms it is probable that an increased peristalsis is at hand in most instances. It is also very likely that many cases of so-called nervous diarrheas on careful examination will be found to belong to this class. In the pancreatic forms, large fatty stools, usually soft but occasionally diarrheal, aid us in reaching a correct diagnosis. In the suprarenal forms, the diarrhea is due to a disturbance of the internal secretion of this gland producing a hyperperistalsis. The intestinal secretions are not ordinarily disturbed in this affection. Five cases of diarrhea due to disturbances of the internal secretions were noted in my series.

DIARRHEAS OF TOXIC AND UNDETERMINED ORIGIN

There still remains a class of diarrheas, the origin of which has not yet been fully determined in all instances. In this class are included those forms in which the irritation is transmitted through the circulation. I refer especially to the diarrheas of nephritis, gout, cirrhosis of the liver, and to the various circulatory disorders, as well as to certain other diseases, such as sprew and pellagra. In some of these instances a catarrhal condition is present, while in others no special lesion is produced and the changes that are observed in the intestinal canal are purely secondary lesions. Diarrhea of nephritic origin is probably due, in the larger proportion of cases, to the excretion into the bowel of irritating toxins, as is shown by the fact that the severity of the diarrhea varies with the exacerbations of the nephritic disease. In patients affected with chronic nephritis extending over a long period of time, uremic ulcers have been observed in both the small and the large bowel. In this series there were eight cases of diarrhea of toxic origin.

I have attempted briefly to describe some of the most important forms of diarrhea due to enterocolonic conditions. The diagnosis of some of these forms is exceedingly simple, while in the larger proportion of cases it is most difficult. It is highly important in all instances to make a thorough study of all features, utilizing all diagnostic measures to ascertain the underlying cause. Only in this way can therapeutic measures be instituted which may prove of the greatest avail.

RECTAL AND SIGMOID CONDITIONS IN CHRONIC DIARRHEA *

JOHN L. JELKS, M.D.
Fellow of the American College of Surgeons
MEMPHIS, TENN.

The conditions found in the rectum and sigmoid flexure in cases of chronic diarrhea differ very markedly, and they may be due to numerous causative factors.

1. They may be caused by a primary infectious agent, which may be an amebic, a bacillary or a flagellate infection, or some other infectious element which may persist over a long period of time.

2. The conditions may be due to the primary and some secondary etiologic factors, as when during the course of a proctocolitis, the primary cause of which was a bacillary or flagellate infection, the patient becomes infected with the pathogenic ameba. The case may be one primarily of amebic infection, which, though it has continued over weeks or months, or even years, may not have produced alarming symptoms, until some secondary infection ensues, which may convert a seemingly indifferent situation into one of alarm, with possibly fatal results.

3. They may be due to the primary pathology, which was produced by the primary etiologic element or infection, though the latter may have been controlled, or may have disappeared entirely; hence, we have observed very extensive rectocolonic ulcerations due primarily to the ameba infection and secondarily to a streptococcic invasion, and though we had controlled the ameba infection, as we believed, the mucous membrane slough has been so extensive that the ulceration persisted for a long time, and the natural result was that the diarrheal symptoms also persisted.

4. A chronic diarrhea has oftentimes been observed to persist after all primary etiologic factors and all

---

* Read before the Section on Gastro-Enterology and Proctology at the Sixty-Eighth Annual Session of the American Medical Association, New York, June, 1917.

primary pathology have disappeared. This, I believe, occurs most often as a result of a late pathologic condition, such as adenomas, syphilis, and newly formed membranes.

5. There are also contributory physical and systemic diseases and conditions in which a persistance of the diarrheal symptoms are found. In some of these the rectum may present only a red and glazed appearance, or may appear quite normal macroscopically. At this point I might mention, for the purpose of discussion, some cases of so-called mucous colitis, which have followed certain operations, or which have persisted long after an intestinal infection has been controlled, and all ulcers in the rectum and sigmoid have healed, but if the abdomen is reopened, there may be found, as I have observed in some cases, a pericolic veil-like process extending over greater or less areas of the sigmoid colon. These veils are very delicate in structure, and are not closely attached to or adherent to the wall of the intestine. To these also may be due the kinks that I have found in some such cases of mucous colitis. With this class of cases I might also associate the persistent and almost uncontrollable diarrheas of cirrhosis of the liver, and those of diabetes and acidosis.

It has appeared to me a rather remarkable fact that in all the voluminous writings on the subject (chronic diarrhea) I have found very few references to even the gross pathology. Owing to the sudden and continued illness of an able pathologist who had promised assistance, I have been forced to omit minute pathology, which I believe is of importance and would have been of rare interest.

The conditions found in the rectum and sigmoid in chronic diarrhea are dependent on other factors than the chronicity of symptoms, for the diarrhea may persist long after the pathologic condition in the rectum and colon, which were the primary causes of the diarrhea, has disappeared.

The primary etiologic factor is usually some acute infectious agent; thus, the bacillary infections may continue for a period and the severity of the resulting inflammation may produce erosions and ulcerations, which do not always heal promptly, even though the infectious agent has been destroyed or neutralized. When this is the case, however, we may be confident there is a mixed infection, and in these conditions the streptococcus has played a damaging contributory rôle. In this type of cases, we observe erosions of the epithelial layer, or more or less extensive casts of false membrane may be exfoliated with apparently the entire epithelial layer, or the mucous membrane over great areas may be sloughed off at one time. It must be easily understood, therefore, that recovery from the conditions just described would be necessarily slow, and that for this reason the symptoms would continue to persist. If the infection was primarily amebic, we should expect to find and really do find a more thickened rectal and sigmoid wall, and, too, the rectal valves will have become thickened and unyielding on account of the long continued inflammation, ulceration and fibrosis. The mucous membrane is thick and congested. The intestine does not appear so edematous as is the case in the acute primary processes. The mucosa is covered with a mucopurulent or sanguinomucopurulent coating, underneath which the mucosa is more extensively damaged than would appear, until the coating is washed or rubbed off, when the real extent of gross pathology becomes apparent.

Conditions which serve to stamp a case as a very chronic one are the alternate hypertrophic and atrophic areas, and in some cases I have noticed so much fibrous infiltration of the intestinal wall that stenosis and valvular obstipation have resulted.

On the introduction of the proctoscope, I have observed that the rectum, and less often the sigmoid colon, is covered with a mucopurulent coating, and when this is wiped away, the mucous membrane appears eroded in spots, or more or less discrete ulcers with oftentimes ragged edges will be seen. Oozing appears quite general over these areas, or in other instances the rectal mucosa may seem to be intact, with the exception of a few circinate lines. In some very chronic cases that I have examined, no definite pathology could be found in either the rectum or the sigmoid, except the alternately atrophic and hypertrophic areas of the mucosa previously mentioned, but this was usually in or during a period of abatement of symptoms, when the infectious agent, which was the ameba, was in the encysted state and not creating much disturbance.

The distinctive features I have observed between the amebic rectum and sigmoid colon and the pellagrous or bacillary conditions of the intestines are that in the former the mucous membrane, as previously stated, appears thicker and more edematous and the ulcerations have proved more destructive to the deeper layers, whereas, in both the bacillary and the pellagrous infections the erosions appear more superficial, there is less edema, except in the very acute conditions, and the oozing is from every surface, as if the vasoconstrictors were paralyzed and the blood was oozing from every capillary. Now, while this is the rule, there are marked exceptions; in fact, in some cases the pathology in the rectum and sigmoid was very extensive, as extensive as I have observed in any amebic case.

The conditions found in some cases must necessarily be remittent or intermittent in their severity, otherwise these patients would rapidly become exsanguinated or septic or both, as in fact some do, but apparently with no other treatment than rest, the elimination of carbohydrate diets and the substitution therefor of a diet of milk and eggs, which diet does not supply in the intestinal laboratory a good culture medium, the hemorrhage ceases, the diarrheal symptoms abate, and even constipation may supervene. The intestinal mucosa then assumes a pink or red and glazed appearance, and may for a time thereafter appear quite normal, until the next seasonal recurrence, when the same unhappy course ensues.

If the rectum and sigmoid are examined from time to time between these recurrent attacks of pellagrous diarrhea, the conditions will be seen to vary between these two extremes just described, or the intestine may be congested and coated with mucus, and, after this mucus is wiped away, pin-scratch or circinate lines or discrete erosions may be seen. The intestine may appear blanched, owing to the low condition of the hemoglobin and the inanition, yet, with the recurrence of symptoms the blush and the ooze reappear on both the mucous and serous surfaces. Not only is this the case with the rectum and the sigmoid flexure, but this is the condition we find throughout the colon, including the appendix, and to a certain degree this blush is observed throughout the intestinal tract. I have never observed ulcerations above the cecum in these cases, but the appendix quite often suffers and occasionally perforates. When the intestine is ulcerated the rectum and the sigmoid have always appeared to suffer the greatest degree of pathology.

A condition follows, or is associated, in a limited number of these chronic intestinal infections, amebic and pellagrous or bacillary, which may give rise to a more or less persistent diarrheal disturbance. I refer to adenomas and syphilitic condylomas. The diarrhea will usually persist as long as these growths remain; especially is this true when adenomas are present in numbers, and their removal affords prompt relief. In some of my amebic cases I have observed these adenomas in great numbers, and in one pellagrous case in which I recently performed an appendicocecostomy one of the very large adenomas sloughed and came away.

Some of these tumors have been reported malignant by able pathologists; yet, after their removal with the curet or cautery they have never recurred. Their most frequent location has appeared to be either on or at the base of the rectal valves; however, I have observed them studding both the rectum and sigmoid colon in great numbers.

I have observed in many instances a mucous diarrhea persist for months and years after a primary infection and pathology had disappeared from the rectum and the sigmoid, but a pericolitis had developed, which resulted in the formation of pericolic veils and kinks. The rectum and the sigmoid may appear quite normal in these cases, and no complaint of pain or disturbance is made that could be referred to the lower intestine. These pericolic veils, I believe, are more often found in the South, where infections of the intestine are more common and especially pellagra.

I do not wish to be misunderstood or misquoted in regard to this subject, for I do not refer to such conditions as the bloodless fold of Treves, which I believe are of a different origin and are productive of stasis, while these veils are more often associated with so-called mucous colitis. These constitute a late pathology; hence, in the majority of these cases the rectum and the sigmoid appear normal.

ABSTRACT OF DISCUSSION*

ON PAPERS OF DRS. GANT, FRIEDENWALD AND JELKS

Dr. Charles D. Spivak, Denver: We have neglected physical therapeutics. It took a century, probably, before we found out that air is a good therapeutic agent. We all agree that rest is a therapeutic agent. So is work. All our functions are alternating between rest and work, and yet we do not know how to use rest and work as therapeutic agents. In acute cases of diarrhea hardly any one thinks of prescribing a diet at the first visit. In a case of acute vomiting, no sane person would insist on feeding his patient. The physician would rather order no nourishment, in spite of the great concern, perhaps, of the relatives that the patient has been starving for ten or fifteen hours. When we come to chronic cases of diarrhea or vomiting every writer speaks of a "suitable diet," and nobody knows exactly what a suitable diet is. A sufferer from lung disease uses a physical agent, namely fresh air. The modification of the quality and quantity of the air makes it a therapeutic agent. In chronic diarrheas, the stomach and intestines are irritated. The introduction of food adds insult to injury. It is rational to employ the physical therapeutic agent, rest. Modify the quantity of rest. Leave the intestines and stomach alone for a day, for two, for three, for ten if necessary. I have not yet seen a case of diarrhea, when not complicated by severe pathologic conditions, that would not yield to absolute rest, and absolute rest cannot be secured except the stomach and intestines are not functionating in their digestive capacity. The principle of rest applies to any other organ of the body when irritated, bruised or broken. There is no need to fear having patients abstain from food for one day or ten days. The treatment of appendicitis and peritonitis has taught us that we can keep our patients without food for weeks. The more recent treatment of diabetes by starvation is another plea for the efficacy of rest or abstinence from food as a therapeutic agent of great value.

Dr. Chittenden Hill, Boston: The duty of the large intestine is the absorption of water from the waste. In the colon absorption is accomplished by reversed peristalsis, the water being thrown back into the caput coli where it is absorbed. Material on reaching the descending colon, normally, should be nearly as dry as in the rectum, but should not be so hard and inspissated that the mucosa of the rectum or sigmoid is injured. For obvious reasons civilized man has attempted to establish an artificial habit with respect to the function of defecation, so that one movement of the bowels daily has come to be regarded as normal. A more frequent occurrence is always an occasion for worry and is considered a diarrhea by most people.

The newer physiology of the intestinal tract teaches us that there are several periods throughout the day when peristaltic waves are excited, as by eating or drinking, that would result in defecation had we not almost from childhood disregarded these natural stimuli. In other words, were it not for the dictates of convenience, mankind would more closely resemble the higher animals in respect to emptying the bowels and not become resigned to a fixed routine of infrequent defecation.

Dr. Nathan Rosewater, Cleveland: Dr. Friedenwald's scientific classification points to a more rational therapy. I agree with Dr. Spivak that rest in essential. After using my abdominal plaster bandage for twenty years, I would not treat chronic diarrhea without supporting the abdominal wall with this bandage, whereby irritations and atonicity from ptosis are avoided. The surgeon uses splints to immobilize. So can we to advantage. By using hydrochloric acid over long periods in achylia the neuroglandular function of the stomach can be rested a long time with benefit and may finally refunctionate. Plenty of carbohydrate food gives the necessary alkali desired by Einhorn, so that in spite of added hydrochloric acid as an essential activator the blood content is undisturbed.

Dr. Frank C. Yeomans, New York: Amebic dysentery in this latitude is very insidious and much milder than in the tropics. We very rarely see an abscess of the liver, gangrene or perforation of the bowel. A single course of emetin acts as does a single course of quinin in malaria. Resistant cystic forms may develop later on, and the symptoms recur unless several courses of treatment are given at intervals. After secondary infection of the amebic ulcers has occurred, emetin alone will no longer be efficient. Then we have to resort to irrigations either through the rectum, or an enterostomy, or else autogenous vaccines and other forms of treatment.

One other form of bowel tuberculosis to be emphasized is the hyperplastic. Tuberculoma cannot be distinguished clinically from a malignant growth. Preoperative diagnosis of the nature of this tumor is not essential, for we have a growth which is practically malignant and has to be removed surgically.

Dr. Friedenwald did not mention a serious form of colitis which is difficult to treat, namely, so-called hemorrhagic colitis. The chief symptom is frequent stools, consisting mainly of blood; the blood seems to ooze from the mucosa everywhere. The exact etiology is not known, but the pathology has been studied. I cured three patients with fluid-extract of krameria, alternating with argyrol, 25 per cent.

Dr. J. Rawson Pennington, Chicago: We have heard today that diarrhea may be caused by pyorrhea, achylia, stasis, proctitis, overeating, etc. If this is true, and I believe then diarrhea is a symptomatic or a secondary d
treatment should consist in locating the

---

* The first paper in this symposium on "The Surgical Treatment of Chronic Enterocolonic Diarrhea," by Dr. Samuel C. Gant, New York, appeared in The Journal last week, page 1603.

and removing or correcting it, which is necessary to cure the trouble. But when a patient with diarrhea has all the conditions above mentioned, and more too, perhaps, how are we to differentiate and determine the one that is causing the diarrhea? This is the most important question of all. That settled, we will then know whether or not to starve the patient, advise marriage, do a colectomy or a sigmoidostomy, advise the wearing of an abdominal support or give bismuth, etc. But to follow or advise one or the other of these procedures before making a diagnosis is certainly not to be commended.

Dr. Alfred J. Zobel, San Francisco: The giving of frequent irrigations in colitis sometimes keeps up the diarrhea. Great caution must be used. The strength of the solution, and just what is used, is of vital importance. Even the use of a solution containing 1 grain of potassium permanganate to a quart (one of the drugs mentioned today as being of value in intestinal irrigation), when introduced through the sigmoidoscope so that we know it is in the sigmoid and not in the rectum at all, will soon cause griping pains in the abdomen, and the patient will desire to have a rapid evacuation of the bowels. I therefore say again, that in conditions in which we use irrigation, we may err by continuing the irrigations too long, and by using too strong solutions.

With Dr. Friedenwald I must also take issue, as he made the statement that it was easy to diagnose syphilitic ulcers of the rectum. I cannot do it, and all with whom I have spoken say that they cannot diagnose this condition easily. As a matter of fact I have found that it is very difficult to differentiate between beginning carcinoma and a syphilitic condition of the rectum.

Dr. Horace W. Soper, St. Louis: Dr. Jelks mentioned the fact that infection may be limited to the rectum. I recall two cases in which the infection was limited to the rectum where irrigation had washed the infectious material higher and caused general colitis. In this connection the work done by Dr. Rosenberg with the powder insufflation method is interesting. The dry powder method used with the proctoscope will clear up these cases very rapidly. In experimenting with a large number of powders I have found that calomel is the best, inasmuch as it is the most antiseptic of all powders. It is absolutely nonirritating even to the mucosa of the anal canal. Calomel is especially efficacious in the treatment of hemorrhagic forms of proctitis and sigmoiditis.

In response to a question by Dr. R. W. Jackson of Fall River with regard to what precaution is used to prevent absorption of the calomel if it is used in large quantities, or frequently, thus causing calomel poisoning, I answered that calomel, even if used in large quantities in the rectum or sigmoid, is not absorbed. I have used very large quantities, as much as 3 to 4 drams at a time. I believe the reason for this nonabsorption is that the calomel is not broken up as it is in the stomach or small intestine, but that it acts merely as a local antiseptic powder in the lower bowel.

Dr. Harris Weinstein, New York: With regard to the symptoms of carcinoma of the intestine, we are accustomed to consider constipation as the first symptom, but this is not always the case. It is often not a question of constipation, but of retained stool in a section of intestine and then continuous diarrhea on account of the irritation brought about by putrefaction. I have seen any number of cases develop in this way—primarily diarrhea with three to four stools a day, the patient complaining only of distention and foul-smelling stools, but, with the exception of a possible achylia, no gastric symptoms. Appetite and digestion may be excellent. A month or two after the appearance of these symptoms a large mass may be detected in the intestine. Then only obstructive symptoms appear, due not alone to the tumor, but also to spasm caused by irritation of the mucosa adjoining the mass.

Diarrhea in chronic appendicitis is rather rare, but we do meet with cases in which there is diarrhea. Some of these cases terminate in acute gangrenous appendicitis. In pancreatogenous diarrhea the stool is so characteristic that it cannot be mistaken for any other condition.

Dr. J. W. Weinstein, New York: Although my predecessor, Dr. Weinstein, repudiates the starvation treatment, I shall give it the highest endorsement. The statement that patients will not stand for it is not in keeping with my experience. I have tried it for as long as three weeks and the people will submit to it. Of course, we must sometimes modify the treatment, as Dr. Spivak said. The surgeon makes a rectal fistula and gives rest to the colon. We can do that in a milder way. Just give the patient water instead of food, and in some patients the juice of three or four oranges a day. Recently I had a patient who had a large ulceration through the rectum. I explained to him that his bowel must be given a rest; that one way was by a surgical operation, namely, by severing the terminal ileum from the cecum, implanting it temporarily in the abdominal wall, this to be followed later by a second operation, or another way was by means of starvation. He submitted to the starvation method and I can report a favorable result in this case.

Dr. Dwight L. Murray, Syracuse, N. Y.: We must always remember that only about 25 or 30 per cent. of the bowel elimination is the result of food, the débris of food, and that the balance of it is brought down from the stomach and deposited as ash or worn-out material.

Dr. Samuel G. Gant, New York: When appendicostomy fails to relieve or cure chronic diarrhea usually the irrigations are too small or the bowel is always washed out with the patient in the same position, which prevents the fluid from reaching lesions on different sides of the bowel. The benefit derived from bowel flushing is due as much to the mechanical action of the fluid in ridding the intestine of toxins and irritating débris as to the contained chemical. I have obtained the best results with 2 per cent. ichthyol irrigations.

Dr. Julius Friedenwald, Baltimore: It is impossible in so short a period of time as was allotted to me to discuss all of the questions concerning the treatment of chronic diarrheas. In my paper I especially wished to call attention to the importance of etiology. It is very important, if the treatment is to be successful, to clear up the diagnosis; and it is therefore extremely important to study every case carefully, and as far as possible reach a conclusion as to the etiology.

In regard to the treatment of special conditions, I heartily agree with many of the speakers regarding the efficacy of rest in most forms of chronic diarrheas. As to absolute starvation, I have had no experience with this special form of treatment, though we all know the importance of diet in the treatment of chronic diarrheas, and of allowing just as little food as possible. The use of the abdominal support is very valuable, especially when there is the slightest degree of enteroptosis.

Dr. Julius Friedenwald, Baltimore: Regarding the use of emetin, I feel with Dr. Yeomans that it is necessary to repeat the treatment frequently; that one course is not sufficient, and one is forced to repeat the treatment every few weeks or months so as to secure permanent benefit.

Dr. John L. Jelks, Memphis, Tenn.: In attacks in which the diarrhea and toxicity are due to regurgitation into the ileum from the colon, physical rest of the intestine is important, of course. But there is not much rest if the intestine is infected and irritated by bacteria or by some other infectious agent; but if there is a hole in the intestine, by turning clean, or salt, or some aseptic water into it and washing out the irritating stimulus, I believe the more important rest is then made possible.

As to chapparo amargoso, that is very difficult to obtain in this country. I have had no experience with it. It takes a lot of it to conduct a few treatments, and it comes from Mexico.

As to emetin, do not be too sure the emetin kills the amebas. Be less sure the emetin acts as a destroyer of the amebas; be overly sure to cure the ulcerations resulting therefrom, the walls of which contain amebas. Moreover, there are fixed amebas, some cases of which no emetin will cure.

Bismuth in teaspoonful doses every three hours in courses in these chronic cases is appropriate. Formaldehyd-boric solution I know destroys every ameba it comes in contact with. Iodin solutions are exceedingly beneficial in many cases. Do not use the irrigations too long or too strong. Sterile water solutions at times are better than strong solutions.

Syphilitic cases must always have salvarsan, if possible, before serious surgery is practiced. Vaccines, especially autogenous, are beneficial and indicated in many cases.

GASTRIC CONDITIONS IN SPASTIC CONSTIPATION *

WILLIAM G. MORGAN, M.D.
WASHINGTON, D. C.

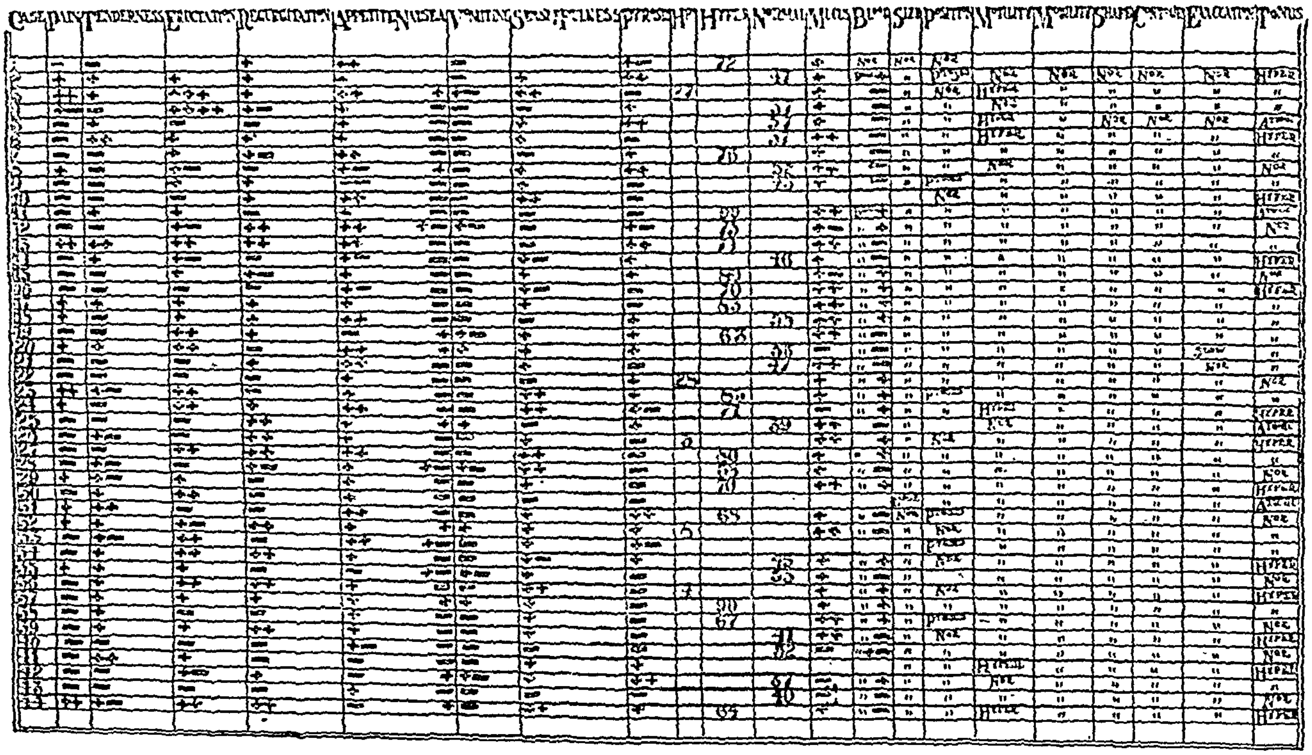
A study of the gastric condition in purely spastic constipation, if indeed there is such a condition, should cover a critical survey of many hundred cases in order that the deductions drawn may be of practical value. For this reason I offer, with full apology, my series of only forty-four cases, which have occurred in my practice during 1917.

Now, turning to a consideration of the objective symptoms, we find that hypertonia of the viscus was present in a large majority of the cases of this series.

STUDY OF THE GASTRIC CONDITIONS IN SPASTIC CONSTIPATION

		No.		No.
Pain	Present	15	Absent	29
Tenderness	Present	25	Absent	19
Eructation	Present	24	Absent	13
Regurgitation	Present	27	Absent	17
Vomiting	Present	10	Absent	34
Fulness	Present	32	Absent	12
Pyrosis	Present	24	Absent	20
Appetite	Present	39	Absent	5
Nausea	Present	13	Absent	31
Mucus	Excess	34	Normal	10
Benzidin	Positive	18	Negative	26
Size	Normal	42	Negative	2
Position	Normal	36	Negative	8
Motility	Normal	37	Hyper	7
Mobility	Normal	44		
Shape	Normal	44		
Tonus (hypo 2)	Hyper	26	Normal	16
Evacuation	Normal	43	Slow	1
Acidity (hypo 2)	Hyper	17	Normal	17

On fluoroscopic examination, twenty-six revealed spastic contraction of the stomach; whereas two were atonic and normal in this respect.



A study of the gastric conditions in spastic constipation.

Obviously it was proper to include only those cases in which a careful roentgen-ray study has been made. Furthermore, I have excluded those cases in which other pathologic conditions, such as chronic appendicitis, chronic cholecystitis or peptic ulcer, were found. In other words, I believe that all the cases reported are chronic spastic constipation.

Of this series twenty-four had pyrosis coming on before meals, while twenty-nine experienced no pyrosis. Twenty-seven complained of acid regurgitation from one-half to two hours after eating, and seventeen did not have it. In thirty-nine cases the appetite was normal or increased, and in five the appetite was absent. Ten of these patients complained of vomiting and thirteen of nausea.

The time of evacuation was normal in forty-three and retarded in one case. The stomach was normal in shape and mobility in all the forty-four cases under consideration; and all but two were of normal size; these two were dilated. In thirty-six cases the stomach was in the normal position, and eight cases showed more or less ptosis. In seven cases hypermotility was present, and in thirty-seven normal motility.

Studying the gastric secretions, we noted that seventeen cases showed moderate hyperacidity with hypersecretion, ten showed subacidity, and seventeen, normal values.

Abnormal amounts of mucus were recorded in thirty-four of the forty-four cases. This coincides with many observations in the past, that whenever we find the stomach the seat of spasmodic contractions, if continuing any length of time, we find a chronic con-

gestion of the mucosa with an increased production of mucus. It is in this class of cases we get the bloody smear on the duodenal thread, which is so different from the characteristic short, definite stain, mostly confined to one side of the thread, found in peptic ulcer. To bear out, somewhat, my assertion in this regard, there was a positive benzidin reaction in eighteen of the forty-four cases, showing an engorged mucosa, which is easily disturbed by the stomach tube.

1624 I Street.

ABSTRACT OF DISCUSSION

Dr. I. H. Levy, Syracuse, N. Y.: It is rather unfortunate that the words physician and physic come from the same root. The laity expect the physician to dispense physic and the physician cannot entirely get away from this idea. Constipation may occur with any gastric condition, and, on the other hand, may produce almost any stomach symptom, and it is often difficult to decide which is cause and which effect. Constipation is frequently associated with those gastric conditions which result from the taking of insufficient food. These patients, owing to their stomach symptoms, eliminate one article of food after another until they eat so little that obstinate constipation results. The constipation aggravates the gastric symptoms and the resulting weakness the constipation. This produces a vicious circle.

There is another form of constipation found with these cases, described by Hertz as dyschezia. In our roentgen studies we find the barium reaches the ampulla within twenty-four hours, but remains there for days. The abdominal muscles either lack the power to expel the feces, or the tightly contracted sphincter retains them. I prefer to use the more recently suggested classification of rightsided and leftsided constipation, instead of atonic and spastic. Leftsided constipation may exist without causing any symptoms. Rightsided constipation, on the other hand, owing to the absorption of poisonous products from the cecum, may give rise to marked symptoms of autointoxication. In a certain percentage of these cases there is also an open ileocecal valve, and the feces may regurgitate into the ileum. The worst cases of autointoxication I encounter are of this type.

Dr. Louis M. Gompertz, New Haven, Conn.: Three capsules each containing 10 grains of lampblack were given to thirty persons at different times during the day and the number of hours required for the appearance of the black in the stools was noticed. All of these persons were accustomed to having a movement of the bowels each morning. The result of this experiment showed that it required from twelve to fifteen hours before the lamp black could be identified in the feces. After this was done I took 100 cases of habitual constipation, just running through my records, without any attempt at selection, and noted the results of the gastric analyses. Eighty-seven of these cases showed hyperacidity while the remaining ones showed a subacidity or a normal gastric content. It has been pointed out by Schmidt and Strassburger that hyperacidity is an important factor in chronic constipation. It was explained by them that the hyperacidity causes a very perfect absorption of the foodstuffs in the intestines by diminishing the number and retarding the growth of intestinal bacteria, and on account of this a very small residue is left, and then there exists the condition known as spastic constipation. Since this investigation was brought about I have paid particular attention to the gastric conditions in chronic constipation and I have observed that in cases of spastic constipation the symptoms almost always point to hyperacidity in the gastric contents. Whenever the contents are examined, hyperacidity is often present, and I believe it to be an important factor in predisposing a patient to chronic constipation.

Dr. Max Einhorn, New York: In cases of spastic constipation we must rely wholly on symptoms from the beginning, so we must know what we are talking about. Spastic constipation is a variety of constipation which is characterized by too infrequent evacuation of the bowels, and pains during the defecation. Occasionally these fecal masses come out containing mucus and sometimes even a trace of blood. In the ordinary form of chronic, atonic constipation we do not find these symptoms. There is never pain combined with defecation, never mucus, or rather exceptionally do patients complain of that, and never any blood.

Dr. Morgan said that in almost all of these cases he found a normal position of the abdominal organs; in only two, I believe he said, was there any abnormality to be found. In my own cases, as far as I could see, where spastic constipation was present (the definition of this term to be applied as I expressed it) it was principally associated with marked enteroptosis. Again, I have observed that in these conditions hyperchlorhydria is not as often found as in the ordinary forms of constipation.

It is one thing to say that in cases of constipation we find these conditions present and quite another thing to say that these gastric anomalies produce the constipation. I tried to show in a certain variety of conditions of the stomach, hyperchlorhydria and achylia, that constipation in such cases may be caused by anomalies of the stomach. In that way I believed we would leave the constipation as it was and not pay attention to it, but simply give the patient a remedy appropriate to correct the gastric anomaly, and see what happened. It was found that in some of these cases the constipation improved by itself, and that is the reason why I felt that constipation in those cases was caused by a gastric anomaly.

Dr. Dwight H. Murray, Syracuse, N. Y.: I have some ideas about constipation and doubtless when I am through speaking you may think I have gone back to the dark ages, and perhaps the notions are foolish. With regard to the causes of constipation, I feel that I must disagree with what has been said about etiology. The primary causes of constipation, so far as I am able to ascertain from my practice, are three, namely (and these I published in 1911): carelessness, ignorance and laziness. You may smile, but let us consider the child from the cradle up. The mother does not understand the necessity of regular attention to this matter by the child. The child grows up without any knowledge of it; the child would rather play than go to the toilet. When he goes to school, he often leaves home without having had a bowel movement. Many children will put it off until the bowel eliminates itself in the underclothing. This thing continues until the child has grown up, and the symptoms (causes) we are talking about are the results, in my opinion, of a constipation that has been brought on by ignorance or carelessness.

I have patients who say that the mother, father, aunts, grandmother, all were constipated and that they have hereditary constipation. There is no such thing. Every normal man is born free and equal so far as muscular activity is concerned. I am not speaking of obstipation, but of constipation. I find that in every single instance when I mention these things to my patients they admit that they are careless.

A business man, for example, on account of engagements in his office neglects his morning bowel movement. A frequent repetition of this brings on chronic constipation and autointoxication. Such patients cannot produce the normal gastric and intestinal juices, and cannot furnish proper nourishment for any of the tissues, and later we begin to have rectal trouble as a result of constipation. Perhaps there is an ulcer in the rectum and then the vicious circle begins; we have the rectal pathology keeping up the constipation and it keeps up the rectal trouble. I believe we must be consistent and differentiate between the results of constipation and its causes.

Dr. Charles D. Spivak, Denver: Dr. Morgan's chart appeals to me greatly. We have not given enough attention to the recording of symptoms. We are gradually coming to understand that all the laboratory methods are not of as great importance as taking down and noting the symptoms that the patients themselves tell us. It may sound unscientific, but we have to learn our lesson from the surgeons who have found that a good history taken from the lips of the patient throws more light on the case than the laboratory can ever expect to shed, and that the initial symptoms, especially, are the things that give the most light. A simple question as to whether the pain came first and then the vomiting, or the vomiting first and then the pain, may change the diagnosis.

Something has been said with reference to the taking of food. The taking of less food is considered a factor in constipation. This is absolutely wrong. When we say "taking food" we mean food in quantities sufficient for that particular man or woman: What may be enough for me is not enough for some one else. I have found that the quantity of food has nothing to do with these cases; that is, that the taking of a large amount of food does not necessarily preclude constipation. I have seen people who eat a great deal and are constipated, and I have also seen women who are not eating enough and they are also constipated. Both are abnormal. People take more food than they should, and when the quantity of their food is reduced their constipation as a rule ceases. There surely must be a mechanism by which this superfluous quantity of food put daily into the stomach starts the inhibitory function of the bowels. As soon as the food is reduced to the normal the natural inclination of evacuating the bowels starts.

Dr. Nathan Rosewater, Cleveland: Dr. Morgan's instructive paper demonstrates that there is no uniform acidity whether movements are regular or not. In my paper on enteroptosis, in 1900, I cited cases of superacidity or subacidity resulting alike in cures following abdominal plaster bandaging, whereas only symptomatic relief followed treatment by neutralization, thus convincing me that many superacidities and subacidities resulted from enteroptosis. I have often observed constipation and head cold occur the next day after loss of sleep from a night call. Tracing these sequences to loss of sleep, resulting in insufficient peristalsis, I always avoid them by taking a laxative before going to bed. Insufficiently resting the nervous system tends toward peristaltic insufficiency; conversely, sufficient rest and sleep maintain the efficiency of the regulating mechanism.

With Dr. Spivak I must differ about humoring those who have no appetite for breakfast. Surely the stomach is empty; nervous muscular and glandular systems have rested much longer than for the other meals. These patients mostly awaken with "that tired feeling" of all their muscles, external and internal. Their muscles of mastication and deglutition, and also the stomach musculature *feel* tired. I insist they must and can eat a good breakfast.

Dr. David Bercinsky, New Haven, Conn.: From what I have heard here this morning I have received the impression that it is not necessary to bring any special proof to bear out one's statements. I will therefore say a few words in reference to the opinion of the previous speaker that constipation is a result of ignorance and negligence and that the speaker was surprised when he heard patients say that constipation was hereditary in their families. I do believe that there is a form of constipation which is entirely dependent on heredity; that it is not always ignorance or lack of care behind it. At least, I have had cases which convinced me of this.

Now, if we do inherit anatomy, why is it not possible that we may inherit abnormal physiology just as well as normal physiology. Inasmuch as constipation or normal evacuation of the bowels depends on the nervous rhythm of the intestinal peristalsis, this peristaltic rhythm may be individual and characteristic in certain families as a hereditary trait.

Dr. William G. Morgan, Washington, D. C.: I did not consider or think I had the right to consider the etiology and treatment in this paper. If I had not unwittingly further contracted the scope and limit of this paper by confining it to spastic constipation, and had considered the gastric conditions in chronic constipation, the small diagram shown would probably have been quite different; and, as one of the gentlemen who discussed the paper pointed out, hyperacidity would have stood well at the head, and as Dr. Einhorn also pointed out, visceroptosis would probably have had a prominent position.

I agree with Dr. Murphy on the three causes for simple constipation. I think that is borne out by any one who takes the trouble to investigate the previous habits in these conditions, and it is in this type that the Christian Scientists claim to cure and do cure, and it is this one disease more than any other which brings to them such an enormous following, and in which they assert the patients often have been to fifty good practitioners but still have their constipation unrelieved. Dr. Einhorn a great many years ago pointed out the best treatment in this class of cases when he said: "Do not think so much of your bowels. It does not make much difference if they do not move for two of three days." Don't let your patients think that their constipation, or chronic constipation, is a thing of serious import. A little regulation of diet, and a total absence of medicine and enemas, and allaying the fear of enlarged joints, or brain disease, or epilepsy, or old age as a result, and a large percentage of these patients will get well of their constipation and will be almost as grateful to you as they are to Christian Scientists.

THE RECTANGULAR FLAP INCISION FOR OPERATIONS WITHIN THE UPPER ABDOMEN*

WILLY MEYER, M.D.
Attending Surgeon, German and Postgraduate Hospitals
NEW YORK

The last decades have witnessed an increasing tendency of operative surgery to emancipation from the time-honored rule of placing the skin incision parallel to the longitudinal axis of the body.

Trendelenburg's transverse incision for operations within the bladder (1882) was one of the forerunners in this direction.[1] Later followed Pfannenstiel's[2] suprasymphyseal transverse incision of skin and fascia with median division of the deeper tissues for operations on the uterus and its adnexa (1898). In 1910, Sprengel[3] of Brunswick demonstrated the advantages of the transverse direction of the incision in abdominal operations. He emphasized that the broad aponeurotic expansions of the three flat abdominal muscles which join and interlace with those of the opposite side in the median line, forming the linea alba, represent the tendinous termination of these muscles. If the latter contract, the many fine, little, tendonlike fascicles and fibers of these aponeuroses are put on the stretch and pressed together. Consequently, a transverse abdominal incision, which divides the aponeuroses in the direction of their fibers, had the physiologic tendency to *approach* the wound borders, while a cut perpendicular to the direction of their fibers, that is, a vertical cut in the direction of the longitudinal body axis, had the physiologic tendency to make the wound borders *gape*. However carefully stitched up, the tendency of the borders of a longitudinal wound during healing, particularly at times of sneezing or coughing, was to separate. Hence the observation, occasionally made, of a reopening of such a longitudinal abdominal incision, if the catgut used for layer sutures had become absorbed or burst, or retaining silkworm-gut sutures of skin and fascia have been removed too early. Hence, also, the placing of fascia retention sutures in the shape of the figure of 8 and otherwise, left in place for two weeks.

Within the last few years more interest has turned to this question also on this side of the Atlantic. A number of articles have appeared dwelling on this subject; Farr,[4] Moschcowitz,[5] and Meyer[6] have called attention to the decided advantage of the transverse incision. On suturing the wound with catgut in layers, a reopening will hardly ever occur.

---

* Read before the Section on Surgery, General and Abdominal, at the Sixty-Eighth Annual Session of the American Medical Association, New York, June, 1917.

Furthermore, even in the event of suppuration following contamination of a transverse wound of the abdominal parietes, it will be seen that the deepest continuous suture line embracing peritoneum plus transverse fascia and posterior sheath of the rectus muscle will hold. The abdominal cavity remains safely closed. Only in one instance have I seen an exception, and that was in a patient who, after an operation on his stomach, developed what seemed to be a typical tetanus, in all probability due to catgut infection. Here, with the boardlike hardening of the abdominal wall, the entire wound, inclusive of the peritoneum, reopened; reclosure with strong silk sutures, through-and-through, proved a difficult task.

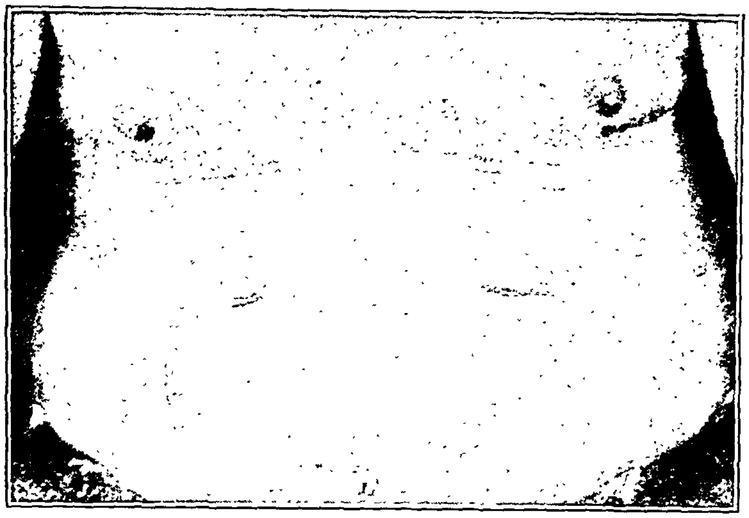

Fig. 1.—Rectangular flap incision with a downward sweep of the right half of the cut within and parallel with the fibers of the right rectus muscle. Case of suspected duodenal ulcer. Appendix only found diseased and adherent in the pelvis.

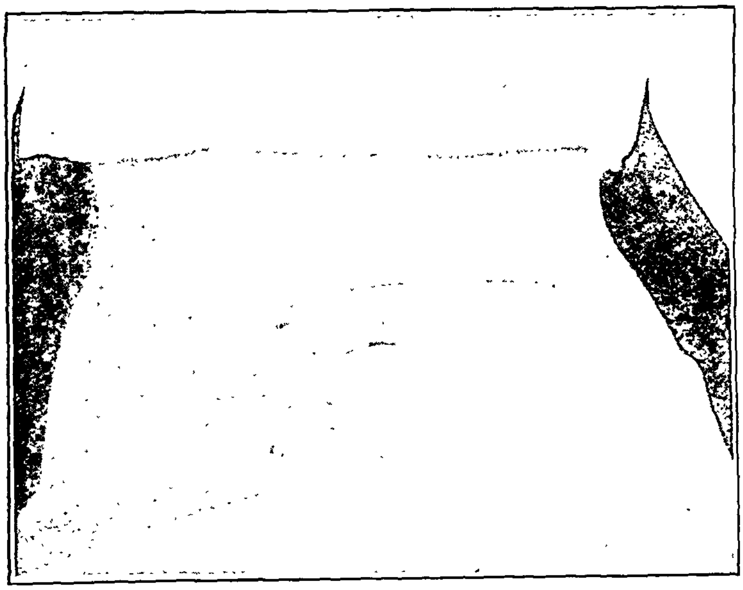

Fig. 2.—Same incision as described in Figure 1, used in a case of sarcoma of the cecum with abdominal and retroperitoneal metastases above and below the umbilical line.

Necrosis of the fascia, not infrequently seen after the perrectal incision, in the case of infection within the abdomen, occurs rarely when the transverse incision is used.

However, a surgeon, making use of the transverse abdominal incision in his daily routine work, cannot help noticing a number of drawbacks or rather defects of this incision. For instance, if the cecal region needs exploration and the patient has a long stretched abdomen, it will often not be easy to pull the parts up into the transverse wound above the umbilicus. Here a turn downward of the right extremity of the incision *within* the rectus muscle, with the possibility of lengthening this part of the incision downward to any desired extent, has proved a good combination in my hands. (Figs. 1 and 2.) For this reason, it is wise not to divide completely the right rectus muscle in the transverse direction. One can then always add the turn and downward sweep, should this indication become apparent in the course of the operation. This rectangular flap incision, with the short leg running downward, has given excellent results in three different cases. It can, of course, be employed equally effectively to the left of the median line, as I had occasion to observe.

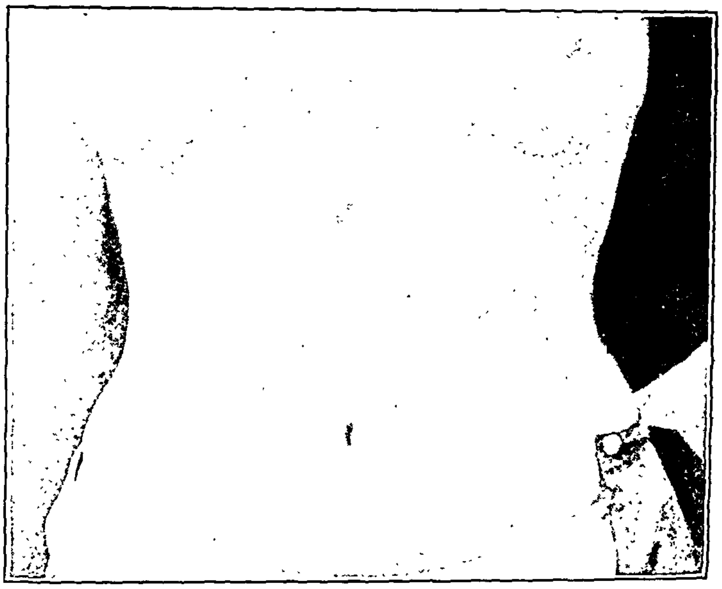

Fig. 3.—Steeply rising borders of the costal arches; they are marked with strips of adhesive plaster.

Further, when employing the transverse abdominal incision for work in the upper abdomen, particularly in gallbladder surgery, the surgeon will notice off and on that the exposure is unsatisfactory. The cause usually is a steep incline of the costal arches (Fig. 3). An additional incision in the median line down to, but not including the peritoneum, will then have to be added to make the upper border of the wound yield; or a horseshoe incision with straight shanks which divides the recti muscles obliquely instead of horizontally (Fig. 4) must be made from the start. It will also be seen, when using the transverse incision in gallbladder surgery, that not infrequently the liver border cannot be turned up well, the step so helpful in some operations of this type.

I have, therefore, particularly since 1915, more frequently made use of the rectangular flap incision also for operations within the upper abdomen, more specifically for operations within the upper right abdomen, namely, explorations of and operations on the gallbladder and bile system. Thus far, only one case has presented itself in which the indication for employing the incision on the left side of the median line could be found.

[6] Meyer, Willy: Ann. Surg., November, 1915.

It is on the basis of this experience that I wish to make a few brief remarks.

There are two different types of this approach: In the one, *all* the layers of the abdominal wall are divided through the same line of incision. In other words, all the tissues that make up the abdominal wall, inclusive of the posterior rectus sheath, transversalis fascia and peritoneum, are turned up in the shape of a rectangular flap (Fig. 5). It is self-evident that thereby the innervation of the abdominal muscles is not interfered with, as only fascias are cut and the muscle substance is divided transversely in the direction of the course of the nerves.

This is the method proposed by Koenig[7] and Kehr.[8]

In the other type of incision only a rectangular *skin-muscle* flap is raised, which includes skin and subcutaneous fat plus the anterior sheath of the rectus muscle and a portion of its belly in the line of the skin incision, while the transversalis muscle and transversalis fascia with the posterior sheath of the rectus muscle—which is made up in this portion of the abdomen, in part at least, by the united aponeuroses of the transversalis muscle and posterior lamella of the aponeurosis of the oblique—plus peritoneum are incised in the oblique direction parallel and in front of the costal arch (Wechselschnitt). The intercostal nerves which feed the muscle substance of the rectus are always clearly exposed and here, too, absolutely preserved. (Fig. 6.) This is the method proposed by Perthes.[9]

1. *Koenig-Kehr Incision.*—When forming the typical rectangular flap by the Koenig-Kehr incision, the surgeon can most advantageously start the incision within or next to the median line (right or left), close to the xiphoid process, and then divide all the tissues of the abdominal wall nearly down to the level of the umbilicus. From this place, when the rectangular turn is rounded off, the skin with subcutaneous fat is divided in a horizontal direction to about the anterior axillary line. Before the outer part of the rectus muscle is divided, its substance can be first fastened to the anterior rectus sheath by the two rows of catgut sutures as employed in the typical transverse incision by Perthes (Fig. 7); the muscle is then divided between them (Fig. 8). If the surgeon prefers, these sutures can be omitted. Then the posterior sheath of the rectus with the peritoneum are divided in the same transverse line.

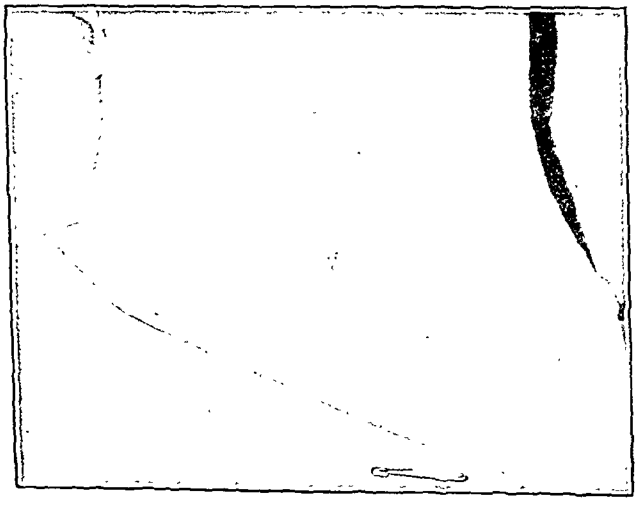

Fig. 4.—Horseshoe incision. Both recti muscles were divided obliquely, parallel with the steep costal arches in a case of gastro-enterostomy with pyloric exclusion for duodenal ulcer.

The access obtained by this incision is an excellent one. Should intra-abdominal conditions require the insertion of drains, these are made to emerge at either the upper or the lower angle, as may be deemed best in the individual case. The suture of the wound is somewhat difficult, but entirely feasible.

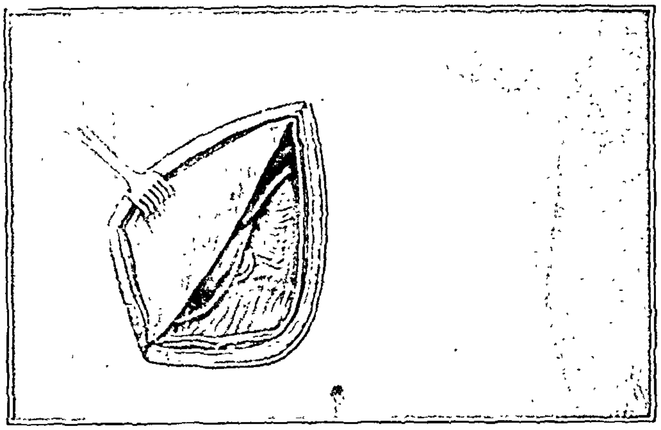

Fig. 5.—Koenig-Kehr incision. All the tissues that make up the abdominal wall are divided in a rectangular line. Sharp retractor pulls on the parietal peritoneum.

2. *Perthes' Incision.*[10]—There is the same arrangement of the rectangular skin incision (Fig. 9), and of the longitudinal part of the cut as in Type 1 (Koenig-Kehr incision), but only down to, not through the posterior sheath of the rectus and peritoneum.[11] This part of the incision requires some care. In women who have gone through a number of pregnancies, the posterior surface of the rectus muscle often forms a firm unit with the thin aponeurotic structures and the peritoneum, all blended into one, rather atrophic, layer. Before the surgeon is aware of it, the peritoneal cavity is opened in the longitudinal, oftener in the transverse part of the incision, or in both, an irritating occurrence, since the hole has to be stitched up, and sometimes it will render impossible the intended division of the deeper layers in an oblique direction.[12] To avoid this accident it is advisable not to start *too* close to the median line and to divide the muscle fibers bluntly, with the handle of the knife. At the lower end of the longitudinal muscle division, just above the umbilicus, the second finger — better the second and third fingers — of the operator's pronated left hand are gently pushed between the muscle substance and its posterior sheath, until a resistance is felt at the outer turn of the rectus sheath (Fig. 10). With the two fingers in position, the two horizontal rows of surrounding catgut sutures are put in place (Fig. 10), the operator's fingers protecting the peritoneal cavity from

8. Kehr, Hans: Arch. f. klin. Chir., 97, 74.
9. Perthes, G.: Zentralbl. f. Chir., 1912, No. 37, p. 1252.

10. During the reading of the paper, the various steps of the operation were discussed with a *motion picture*.

11. If the costal arches *rise steeply*, the incision begins close to the xiphoid process and runs at first parallel with the costal arch. As soon as the place about 0.75 to 1 cm. distant from the median line has been reached, the knife turns downward as shown in Figure 9 (see Fig. 3). This additional incision upward can also be made in the course of the operation, should conditions require more room to do the work.

12. In two patients, one, a very fat man, and the other, a woman who had passed through *many pregnancies*, I found a ventral hernia, the posterior rectus sheath presenting quite a tear. With some care, this fascial hole could be nicely closed by means of a continuous suture, and then the operation continued.

being injured by the needle. The sutures are tied by the assistant, rather tightly. Between them the muscle is cut through (Fig. 11). Usually there is no bleeding at all, thanks to the efficient work of the transverse retention sutures, which not only prevent the retraction of the rectus fibers, but act as a prophylactic hemostatic. For that purpose, the assistant on tying these sutures has to pull on them firmly before knotting. Should the epigastric artery still bleed, it is wise in every instance first to secure and tie the few remaining bleeding points, which is best accomplished with a clamp with a rounded tip (von Bergmann's). Now a sharp retractor raises the skin muscle flap, while, with a gauze mop, the operator separates the muscle from the underlying aponeurotic structures toward the costal arch. Soon the two intercostal nerves with their concomitant blood vessels come into view. About one third inch (1 cm.) in front of these and parallel with the costal arch, the abdominal cavity is incised (Fig. 6).

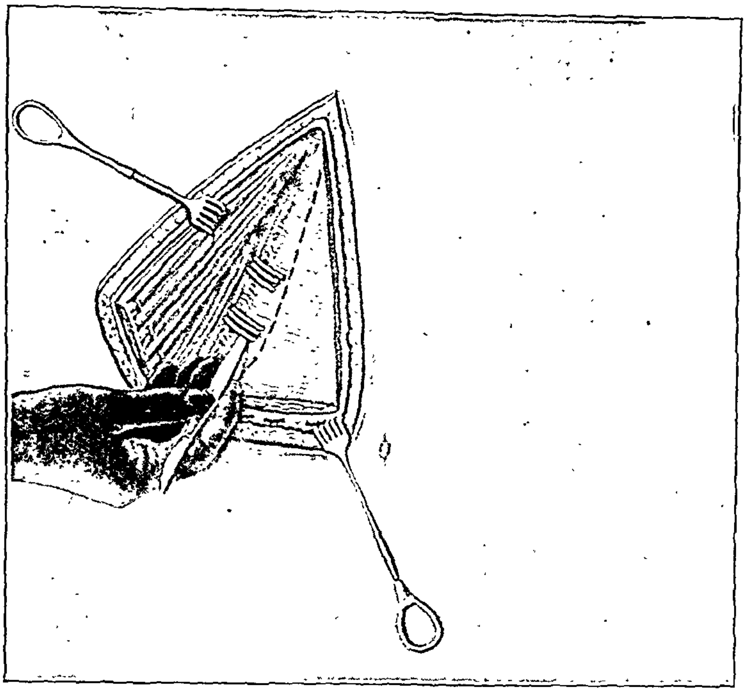

Fig. 6.—First step of Perthes' incision. Rectangular skin muscle flap raised, and costal arch exposed. Two intercostal nerves with their concomitant blood vessels that feed the rectus muscle are clearly in view. Right in front of their exit from the posterior sheath of the rectus, an oblique incision is made parallel with the costal arch.

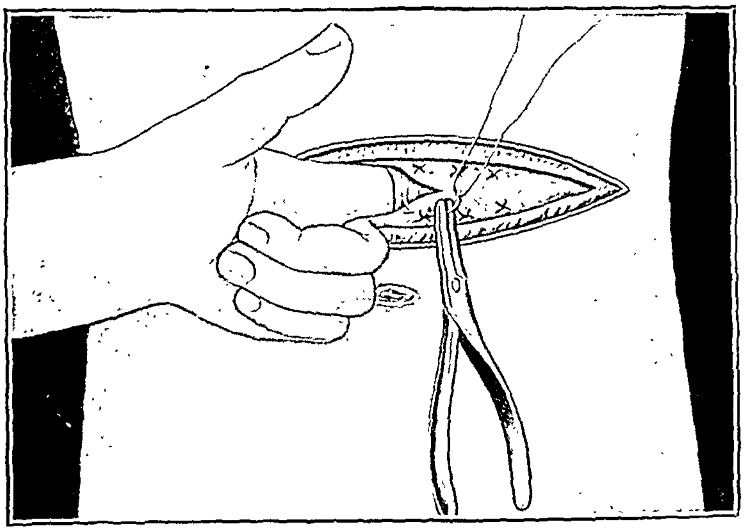

Fig. 7.—Transverse abdominal incision. Left forefinger introduced through a peritoneal buttonhole and three catgut sutures placed above and below with a round curved needle in a horizontal line about 1 cm. apart.

Advantages.—The principal advantages of this abdominal incision are:

(*a*) Wide access is gained to the upper abdominal cavity, much better than by the longitudinal or transverse incision (Fig. 12).

(*b*) There is the same preservation of the muscle innervation as in Type 1, a factor which gains in importance in strong muscular male patients.

(*c*) The incision through the posterior sheath of the rectus and the peritoneum, down to its lower angle, *is nowhere in the same line with the skin incision.* It is situated on a higher level and runs in a different direction than the transverse cut dividing the anterior sheath of the rectus and the muscle, a point which greatly adds to the firmness of the resulting abdominal scar, and thereby guards against the occurrence of a ventral hernia, even in suppurative cases.

(*d*) The oblique cut through the transverse fascia and peritoneum usually meets the very border of the liver, or, in cases of ptosis, its convexity, same as the *Courvoisier incision, which practically* runs in the same direction as the oblique cut in the Perthes incision; however, it divides *all* the layers of the abdominal wall in one and the same line, including the nerves. The liver can be turned upward or pulled out in front of the abdominal wall, as the case may require and the fixation of the liver will permit (Fig. 12).

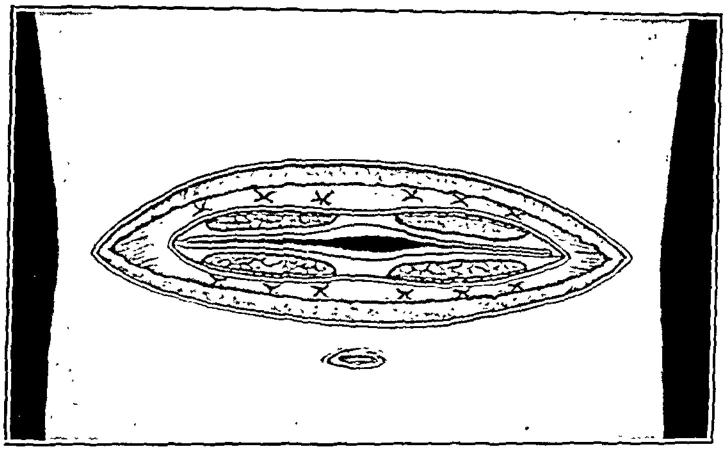

Fig. 8.—Division of the rectus muscle. Both muscles are severed in the transverse abdominal incision, between the two rows of transversely placed catgut sutures *which fasten the muscle substance to the anterior* rectus sheath and act at the same time as efficient hemostatics for the divided epigastric artery and its branches.

(*e*) The small intestines do not crowd into the wound; usually only the omentum and the colon (hepatic flexure), or the omentum, the colon and the pyloric end of the stomach with the duodenum come into view. The small intestines remain protected; less packing is required.

(*f*) On the left side of the median line, the additional cuts made through the seventh costal cartilage near the sternum and from the seventh to the tenth individual rib cartilages near their junction with the bony substance, as needed for the osteoplastic raising of the costal arch (Marwedel) in stomach operations near the cardia, are rendered easier than in Type 1. The costal arch is to be approached in this osteoplastic operation *underneath* the belly of the rectus muscle and *above* the transverse fascia. Here it can be easily and thoroughly exposed (Fig. 13).

Through this abdominal wound, made on the right side, a careful inspection and palpation of the entire length of the stomach, pylorus, duodenum, liver and gallbladder and pancreas are, of course, possible; that is to say, all the organs of the upper abdomen which usually interest the surgeon. Any other desired palpation within the abdomen can also be carried out. In the great majority of the cases, also in patients with steep costal arches, the appendix can be nicely reached and removed, and additional operations on the stomach, for example, gastro-enterostomy, pyloric resection, etc., can be done at the same time.

Should still more room be needed, the horizontal part of the skin wound is somewhat lengthened outwardly, and the three abdominal muscles bluntly separated in the direction of their fibers, as in McBurney's intermuscular incision for appendicitis. If this intermuscular wound is properly held apart, the opening in the posterior sheath of the rectus muscle and peritoneum can be materially increased. I should also think, although I have so far never tried it, that in case of necessity there is no objection to lengthening the longitudinal part of the incision downward, or carrying the horizontal part of it across the median line to the opposite side (Fig. 14), although it seems to me that such a procedure would not be particularly good surgery.

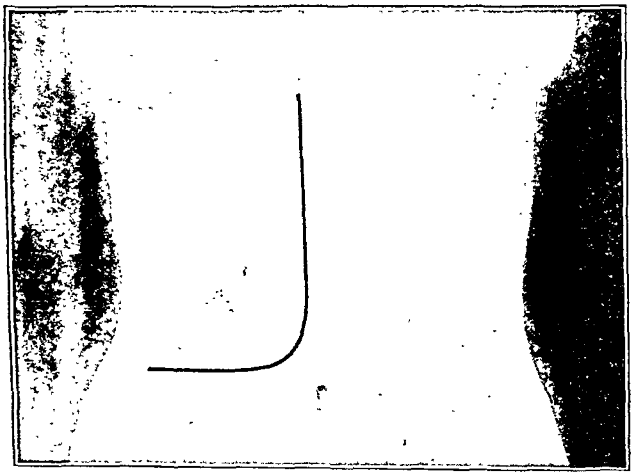

Fig. 9.—Perthes' incision. Line of skin division.

The contents of the small pelvis can, of course, be thoroughly palpated through this incision, but operations on its organs will require a separate incision.

CLOSURE OF THE WOUND AND AFTER-TREATMENT

In closing up, it seems best to bring out the material used for drainage at the upper angle of the wound (Fig. 15). If the hepatic or common duct needs drainage, the normal downward direction of the bile current will induce the operator to make the exit for the drainage tube at the lower (outer) angle.

The suture of the oblique wound of the posterior sheath of the rectus and peritoneum—which tissues are frequently rather thin—to secure best results should commence at the angle which does not harbor the drainage. When this continuous, not interlocking, catgut suture is placed, the patient who, during the intra-abdominal work, has usually been but lightly under the anesthetic, should again be more deeply narcotized up to complete relaxation, and then the upper part of the body raised either by a sandbag or by means of an arrangement of the operating table. If the patient strains, these tissues may tear, although they are strong and resistant, and yield excellent material for safe and reliable union. Should this happen, the tear will nevertheless usually run from the oblique wound in a transverse direction toward the median line, and can be well closed by a few interrupted stitches, after the longitudinal cut has been closed up to the tear, the operator having started the suture from both ends (Fig. 16).

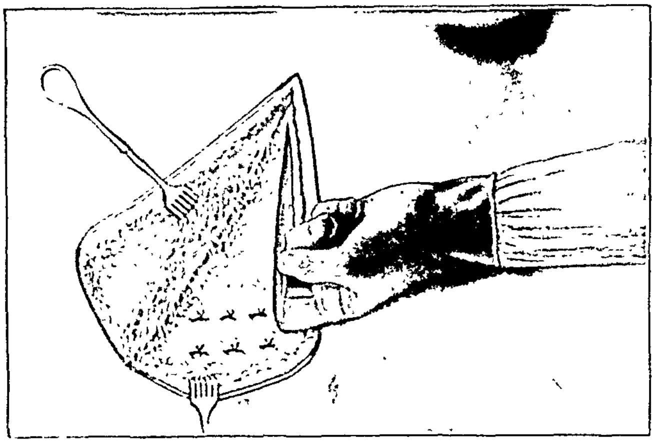

Fig. 10.—Rectus muscle divided bluntly near the median line and in the direction with its fibers. Near the umbilicus, two fingers of the operator's pronated left hand are gently pushed between the substance of the rectus muscle and posterior sheath. Double row of catgut sutures in place, about 1 cm. apart, each completely embracing and compressing a portion of the muscle.

In my last cases, I have sutured the oblique wound in front of the costal arch from above downward, irrespective of the drain exit, because the material to be stitched is more voluminous above than below (transversalis *muscle*, plus fascia and peritoneum), and thus less liable to tear, even if the patient should strain. By close attention, irregularity of the two sides and injury to the abdominal contents in closing the outer angle of the wound can be avoided.

The abdominal cavity having thus been closed, two rubber tissue cigaret drains are placed on top of the transverse fascia—a step of importance because this space must be drained. They emerge at the lower angle of the wound (Fig. 15). Then, the anterior rectus sheath is stitched up (Fig. 15). A clamp, originally placed at the curve of the wound in the anterior sheath of the rectus, will prove of great help in suturing this fascia neatly. One interrupted stitch is first placed at this spot with its ends left long.

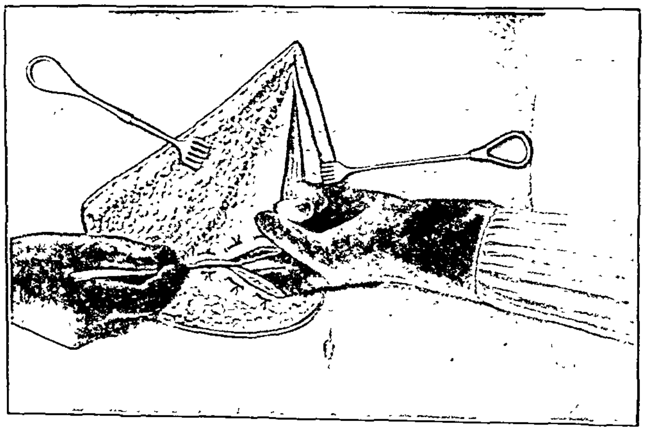

Fig. 11.—Muscle being cut through transversely between the two rows of transverse sutures.

In the longitudinal part of the fascial wound it is sufficient for the needle to catch the wound border internally with some additional muscle tissue externally. When the single suture at the curve is reached, the longitudinal suture is knotted with one of its ends. Another continuous suture is then started.

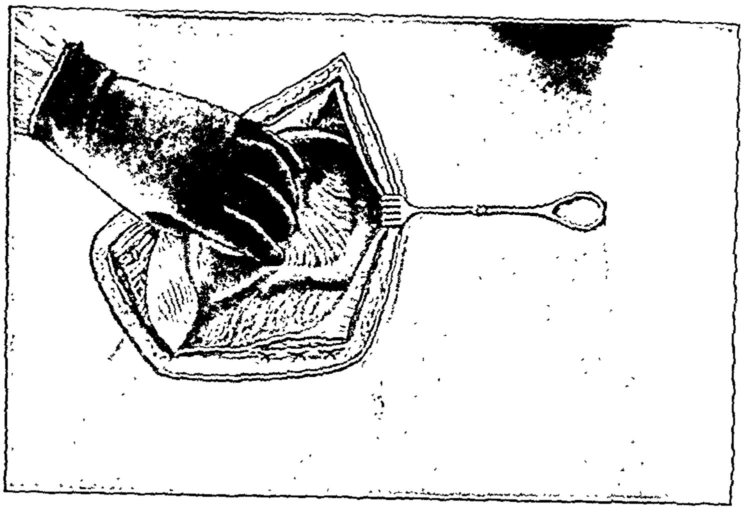

Fig. 12.—Second (oblique) incision finished. Wide access to the liver, gallbladder and bile-ducts and other parts of upper abdomen.

In the transverse portion of the incision, needle and thread take the transversely placed two rows of fascia-muscle sutures in their grasp (Fig. 15). The skin flap is secured by a few silkworm-gut sutures, and the wound is closed by means of a running suture of fine catgut or silk (Fig. 17). After the patient has reached the bed he is placed in a pronounced right-sided Syms' position for the first twenty-four to thirty hours. This position favors drainage and the rapid attachment of the skin-muscle flap to the deeper layers. I have been using this posture for many years in all cases of cholecystectomy, drainage of the bile ducts, perforative appendicitis, etc., requiring drainage, to my greatest satisfaction and benefit to the patient.

PERSONAL EXPERIENCE

Thus far I have made use of the two types of rectangular incision in a rather limited number of cases.

The through-and-through cut (Koenig-Kehr) I have tried but three times; once, a number of years ago in a case of cholecystectomy; the second time, in a patient with suspected duodenal ulcer, when an unintended division of the peritoneum, in the line of the transverse cut, frustrated the contemplated Perthes incision, in which case only a diseased appendix was found and removed; the third time, in a case of cholecystectomy in a multipara, in whom, when the muscle was being bluntly separated from its posterior sheath, the abdominal cavity was unintentionally opened in the perpendicular as well as the horizontal part of the incision.

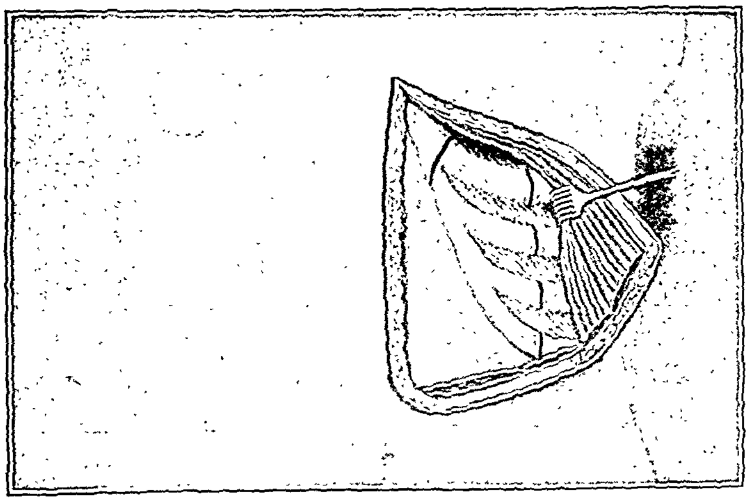

Fig. 13.—Easy approach in Perthes' incision to the left costal arch for making the division of rib cartilages for the osteoplastic lifting of the arch in operations at or near the cardia (diagrammatic).

The typical Perthes incision which was designed for operations on gallbladder and bile ducts has been tried by me in twenty-one patients,[13] in the majority of whom cholecystectomy was done; in one case, additional choledocholithotomy, with subsequent hepaticus drainage, had to be carried out; in two instances, it was employed as a useful entrance for exploration with added appendectomy; once, a subhepatic abscess consecutive to a duodenal ulcer was found.

Perthes himself, at the time of his publication, had tried it in sixteen patients; he praises its advantages.

The number of patients thus far operated on is not large. Still, the number has been sufficient to convince me of the real value of the rectangular flap incision. The Perthes incision, in particular, with the excellent access it affords and the easy closure of the wound, represents a valuable addition to our resources. The strong muscles of an athlete can be thoroughly preserved by it. Not the slightest weakness of the abdominal wall results. There is less tendency to hernia, even in suppurative cases.[14]

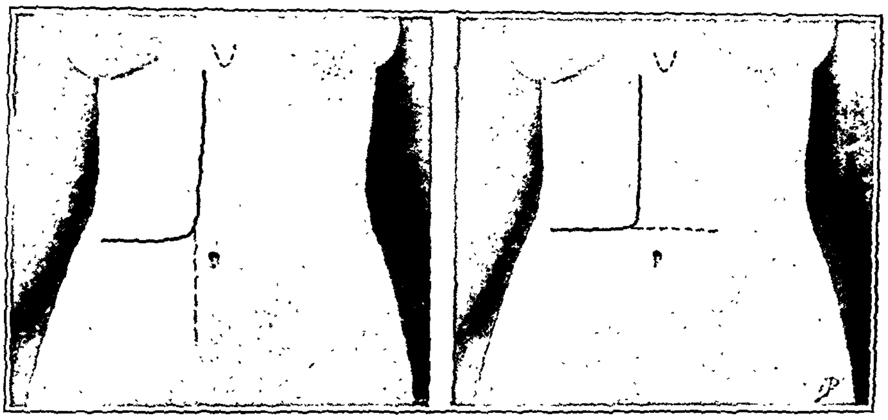

Fig. 14.—Lengthening one leg in the rectangular incision beyond the curve, either way, in case of emergency. (Method not tried; questionable surgery).

In view of the possibility of thorough inspection and wide access to all organs within the upper abdomen, and also our ability usually to remove the appendix easily through Perthes' incision, it seems to me the better policy in many cases of exploration to reverse the usual advance, that is, to cut down oftener on the gallbladder through this incision, palpate and inspect systematically the respective organs, and remove the appendix from this wound, rather than proceed in the opposite direction. The palpating hand pushed up through an appendicular incision can, of course, *feel gallstones*, but it cannot detect, as the operator can by direct visual examination through the rectangular incision, distended bile ducts, adhesions of gallbladder and ducts with neighboring organs, or view the actual condition of duodenum, pylorus, etc.

---

[13] Since this paper was read, one additional operation has been carried out, making in all 22 cases in which the Perthes incision was employed.

[14] In one patient, in whom cholecystitis was suspected in addition to a duodenal ulcer, a subhepatic abscess (streptococcus infection) was encountered. The gallbladder rested on the posterior parietal peritoneum and did not require removal. Here the space beneath the skin-muscle flap was temporarily drained with gauze tamponade and several rubber tubes. Although in the course of the following purulent discharge from this wound, the transversely sutured portion of anterior rectus fascia with muscle substance became necrosed and was pushed off in the shape of a sequestrum, an abdominal hernia did not follow. This observation is in agreeable contrast to the experience which occurs now and then, that necrosis of the anterior rectus fascia with some muscle substance, following the perrectal longitudinal incision for infected intra-abdominal troubles, induces the formation of a ventral hernia.

In other words, by employing the appendix incision the surgeon can only palpate the condition of the organs of the upper abdomen; whereas in the rectangular Perthes incision he can palpate *and inspect*, insuring at the same time a perfect reconstruction of the abdominal wall.

Of course, the rectangular flap incision has not lately been exclusively made use of by me for all operations within the upper abdomen. Quite often the usual longitudinal perrectal approach was selected on either side of the median line, particularly in the female sex and in cases of acute infection demanding quick and immediate interference. Still oftener the typical transverse incision was favored. However, the more I have seen of the advantages of the Perthes incision, the more I feel inclined to try and let exploratory incisions and selected stomach affections also be benefited by it. It will be seen that work near the cardia especially can be made easier by this incision, inasmuch as the osteoplastic resection of the costal arch, as mentioned in the foregoing, appears to be a logical addition.

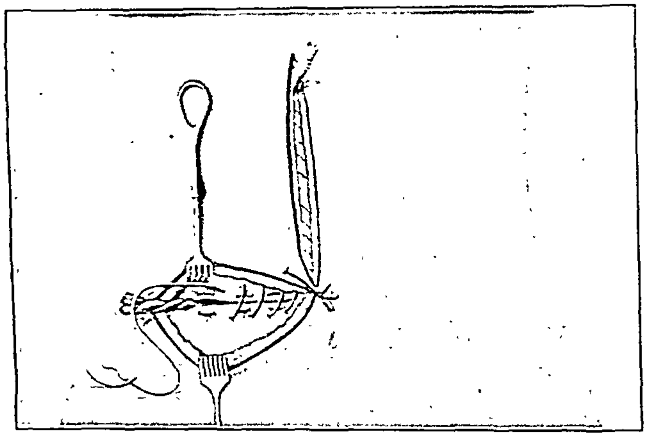

Fig. 15.—Rectangular incision being closed. Rubber tissue drain in bed of gallbladder, covered by the two sutured peritoneal flaps retained from the same, emerges at the upper angle of the wound. (A cigaret drain reaching down close to the ligated cystic duct is added in every case.) Longitudinal part of incision is closed, the transverse one in process of suturing. The thread embraces the transverse sutures. The fixating suture of the angle has been indicated by the artist. It should catch the fascia, not the skin as shown in the illustration, and the skin muscle flap should still be reflected. When suturing the skin, this corner stitch will be found of the same benefit as when closing fascia.

Nevertheless, let us remember that these rectangular flap incisions are only an addition to our operative resources. No one incision represents a panacea. We must adapt the incision to the individual case, and not the case to the incision.

The surgeon will act wisely if he becomes thoroughly acquainted with all types of abdominal incisions that have been found to be of value and present advantages for certain conditions.

700 Madison Avenue.

ABSTRACT OF DISCUSSION

Dr. Robert E. Farr, Minneapolis: For the past six years I have not made a vertical incision above the navel. Two or three points I wish to take up in particular:

1. In relation to the retraction of the rectus muscle after incision is made, there is no reason for putting in the sutures except for the purpose of hemostasis. Measurements made in 150 of my cases show an average of 1 cm. of muscle projecting past the fascia, without a single exception. If this muscle does not project from above, it will project from below; our measurements have shown no variation in this respect. A coaptation of the posterior and the anterior fascia always brings the red meat together.

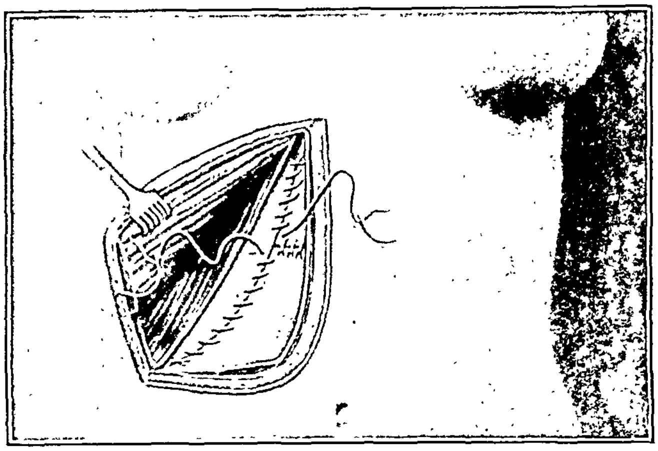

Fig. 16.—Transverse tear in the upper half of the oblique incision. It can be nicely repaired by first closing the main incision, suturing from either end with two needles toward the tear.

2. Unquestionably there is more hemorrhage in these cases than when vertical incision is made, but to my mind this is an indication that they will heal better, just as there is better healing in the tissues of the face because of their great vascularity.

3. The researches of Quain of Bismarck, N. D., at the University of Minnesota, showed that when the pararectus incision was made, cutting off one, two or three of the thoracic nerves, abdominal adhesions resulted between the visceral and parietal peritoneum. In the control cases, in which the nerve supply was conserved, no such adhesions were found. This seems to me to be a very important piece of research.

4. In the matter of drainage I differ from Dr. Meyer in that I place the drainage well back, far to the right. To bring out the drain where Dr. Meyer does, the incision must be made further to the left. I like the transverse incision which extends a little past the midline and is then joined by a vertical incision. In two of my cases, in which both the vertical and transverse incisions were made, hernia occurred in the vertical, while the transverse held. Sprengel, also, has reported two such cases.

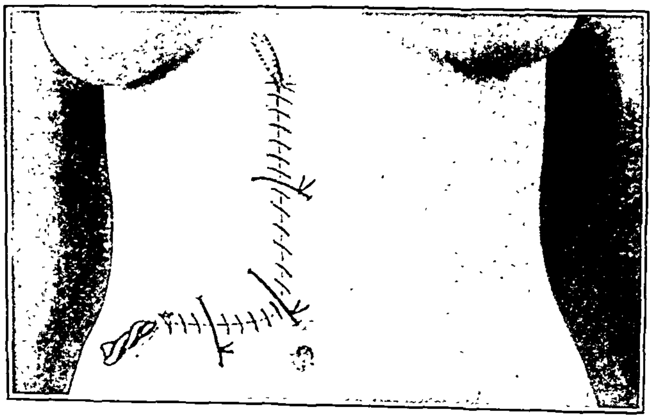

Fig. 17.—Silkworm-gut is used for retention of corner of the skin flap. The same is placed in the middle of the long and short leg of the cut.

Dr. Fred B. Lund, Boston: I have been trying the transverse incision and have found that one cannot get the liver out so well as with the oblique incision. It is so easy to sew up the transverse incision that at first you think you will not do anything else as long as you live. The long oblique incision, however, brings out the liver better. A combination of the two comes nearest to the ideal in a certain number of cases.

Dr. Willy Meyer, New York: I consider this rectangular flap incision to be entirely different from the transverse *incision. In gallbladder surgery in particular I would* prefer the rectangular flap incision. The retention sutures through fascia and muscle I consider an advantage. This incision can just as well be used in the left side. Particularly in operations near the cardia one will find it giving splendid access. I have employed it so far in one case only and could well work close to the cardia. Access can be further improved by an osteoplastic operation on the costal arch. Of course we will not adhere to any one incision, neither the transverse, nor the longitudinal, nor to the rectangular flap; I think we should practice them all.

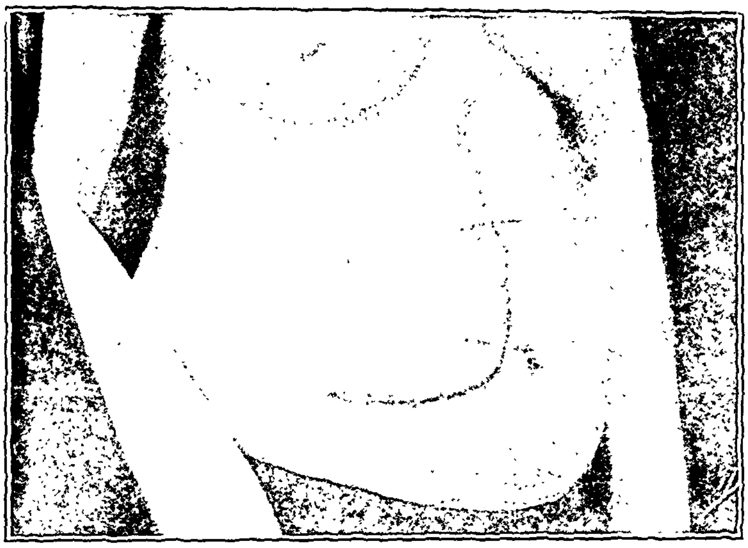

Fig. 18.—Final result. The short transverse scars mark the place of the two upper silkworm-gut skin sutures which had grasped the anterior sheath of the rectus muscle and were left in place for ten days. Securing the fascia in this manner usually is unnecessary, because the two cuts that make up Perthes' incision run at different levels and *in different directions, the skin-muscle flap* covering like a cap the entrance into the peritoneal cavity.

INTRAVENOUS FOREIGN PROTEIN IN THE TREATMENT OF PSORIASIS *

FRANCIS J. SCULLY, M.D.
Research Fellow, Cook County Hospital
CHICAGO

In the treatment of chronic skin diseases which often resist the usual therapeutic measures, any new method of therapy that causes a more rapid and effectual disappearance of the lesions is worthy of investigation. This is particularly true of psoriasis, which is widely prevalent, and many times resists our best efforts to clear up the lesions. On account of its obscure etiology most forms of treatment have been used empirically, which probably accounts for the great variety and diversity of the methods employed.

Chrysarobin, first used by Keith in 1877, is probably the best known remedy, but possesses many disadvantages and does not always relieve the chronic cases. In treating these obstinate cases, strong preparations of chrysarobin have been used; but on account of the dermatitis produced, they could not be applied for long periods of time, necessitating an interrupted and long drawn out course of treatment. Chrysarobin also has the disadvantage of staining the clothing, linen and skin with which it comes in contact. Therefore, any method which will obviate or shorten its use will be of particular value.

Since the exact action of chrysarobin is not understood, it has been difficult to determine what measures will augment its curative effect. The research of Schamberg, Ringer, Raiziss and Kolmer[1] has shown that it has a marked affinity for the proteins of the lesions, especially the scales, but apparently has no germicidal activity. In connection with this study, they also noted that there is a nitrogen retention in psoriasis; however, a restricted protein diet has been tried with only limited success.

In the last four years, intravenous injections of autogenous serum have been employed. At first, this was advocated by Gottheil and Satenstein[2], Fox[3] and Hilario[4] as being a very reliable and efficacious method in the obstinate and resistant cases, though later reports by Fox,[5] and Trimble and Rothwell[6] indicate that it is successful only as an adjunct to former methods of treatment. Along the same line, Perry[7] has used subcutaneous injections of horse serum with about equal success.

Recently Engman and McGarry[8] used intravenous injections of typhoid vaccine with favorable results. They recommended it for further trial, and it was decided to investigate this form of foreign protein therapy in the dermatologic wards of the Cook County Hospital.

TREATMENT BY INTRAVENOUS INJECTIONS OF *FOREIGN PROTEIN*

Eight cases of chronic psoriasis were selected which were resistant, or were responding slowly, to other therapeutic measures. Previous to the use of the vaccine three patients had been using applications of chrysarobin, one ichthyol, and another arsenic internally, each one without marked improvement. These patients all had generalized lesions of the guttate or nummular types, and in four patients the face and scalp were also involved. The duration of the present attack varied from one to seventeen months. All the patients had had previous attacks, which in four cases had entirely cleared up under treatment, while in the others the condition had subsided somewhat, with lesions remaining up to the beginning of the present attack. These patients remained in the hospital during the entire course of treatment. In the mild cases occurring in dispensary patients, this treatment was not employed, as it was not considered advisable to use the vaccine in patients who would not be under observation during the reaction following the injection.

The foreign protein employed in these cases was typhoid vaccine prepared from an active culture, grown twenty-four hours on agar slants, washed off with saline solution, killed by heating at 70 C. for two hours, and preserved by the addition of 0.5 per cent. phenol (carbolic acid). It was diluted so that each cubic centimeter contained 100,000,000.

From three to five injections were given at intervals of from three to four days. The average dose was from 75,000,000 to 100,000,000, the same dose being used for the succeeding injections as for the initial injection. Following the third injection, 2 per cent. chrysarobin ointment was applied daily to the lesions on the body, and 5 per cent. ammoniated mercury ointment to the face and scalp. No internal medication was given.

The reaction following the vaccine was similar to that observed in acute articular rheumatism,[9] except that the rise of temperature and the leukocytosis were not so marked. The succeeding injections were followed by a less marked reaction than the preceding injection. The maximum rise of temperature was to 103 F., and the maximum leukocytosis was 17,600. Headache was noted in two cases, and nausea and vomiting in one case. No other ill effects were observed.

Following the first one or two injections, the lesions became less inflammatory and less indurated, although there was no noticeable retrogression in the extent of the lesions. However, no new lesions appeared. Scaling was also diminished. In two patients who had previously been using chrysarobin, the lesions cleared up rapidly after the injections of the vaccine. In the other patients the condition presented little change until after the application of chrysarobin, following which the lesions disappeared completely in from eight to sixteen days.

The dermatitis resulting from prolonged use of chrysarobin cleared up promptly after one injection of the vaccine. One patient who had been using chrysarobin previously had developed a marked dermatitis. Following the first injection of the vaccine, the itching and erythema disappeared within twenty-four hours. Another patient who had received three injections of vaccine and was using chrysarobin ointment developed a mild dermatitis on the seventh day after the last injection. Following a fourth injection, the dermatitis subsided rapidly.

COMMENT

In general, the results of the vaccine were favorable, considering that only chronic and obstinate cases were treated. The mild cases respond readily, as a rule, to applications of chrysarobin, but in the chronic cases more vigorous treatment is necessary, and it is in these cases that the use of the vaccine finds a place.

When used alone, the vaccine does not clear up the lesions, though it diminishes the induration and inflammatory reaction. However, when used in conjunction with chrysarobin the lesions seem to yield more rapidly than under chrysarobin alone. That the vaccine has some influence and the good results are not due to the chrysarobin alone is illustrated by the three patients who had been using this remedy previous to the vaccine. No noticeable improvement was observed with the chrysarobin until after one or two injections of vaccine, when the lesions cleared up rapidly.

The treatment is simply symptomatic, clearing up the existing lesions, and offers no permanent relief. Recurrences are as likely to follow as when any other form of therapy is employed.

The use of intravenous vaccines has the advantage of easy administration, but has the disadvantage of a more or less marked reaction following the injection, necessitating that the patient remain in bed for from eight to ten hours. The autoserum injections, on the other hand, can be given in the office or the dispensary, but their preparation requires time and care, with a consequent danger of infection.

The dermatitis which results from prolonged use of chrysarobin is easily cleared up. The skin sensitiveness is diminished, and ordinary medication is more effectual and can be pushed without exciting an inflammatory reaction. When a dermatitis is already present, it disappears shortly after the injection, and local treatment is not interrupted. Spiethoff,[10] using injections of autogenous and foreign serum, points out that those dermatoses which in the course of treatment develop an especial susceptibility to chemical substances are amenable to this form of therapy. Luitlen[11] has shown by animal experiments that inflammatory skin reactions are favorably influenced by parenteral injections of autogenous and foreign serum, as also by colloidal substances, in that the skin sensibility is altered toward the irritants applied to it.

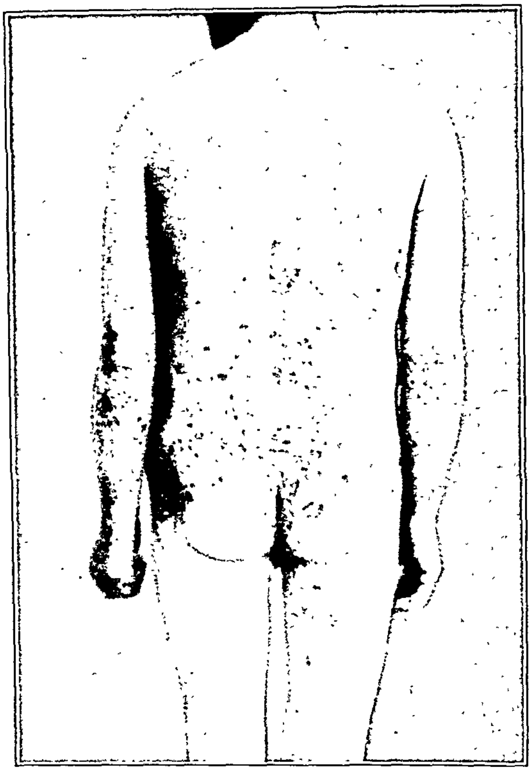

Fig. 1.—Guttate and nummular lesions distributed over the back and buttocks in a case of psoriasis.

The changes which occur following the intravenous injection of vaccine and which result in the retrogression of the lesions are not fully understood. Whether it is due to a mobilization of ferments, as observed by

Jobling and Petersen,[12] with changes in the metabolism, or to a dispersion of the colloids[13] with biochemical changes in the serum, is still a subject of inquiry. Engman and McGarry[8] point out that hyperpyrexia may be a factor, as they observed the retrogression of the lesions of psoriasis in intercurrent infections, as pneumonia and typhoid fever.

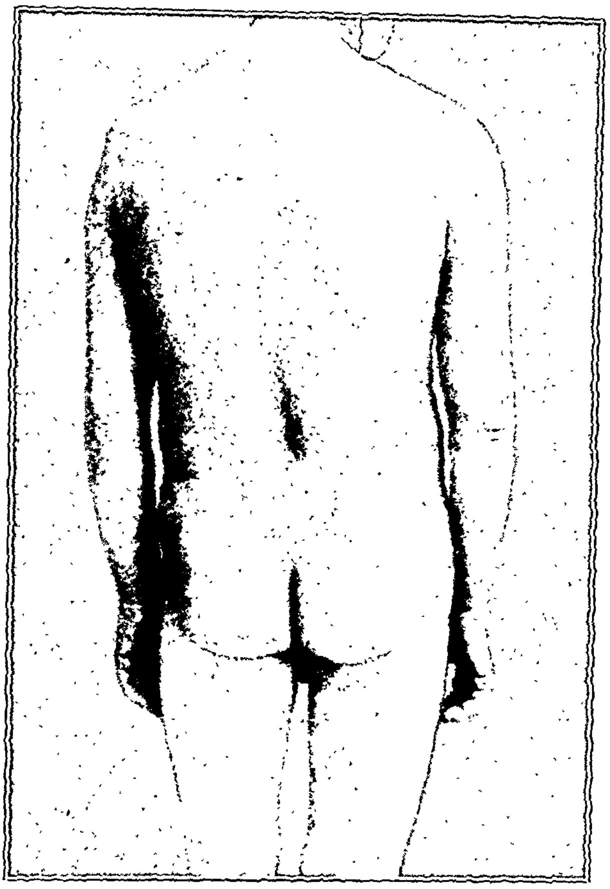

Fig. 2.—Same patient after three weeks' treatment with chrysarobin ointment topically and protein vaccine intravenously. Lesions have cleared up and only slight pigmentation remains.

If psoriasis were of an infectious origin, the effect of the vaccine might be explained on the same basis as in acute articular rheumatism and typhoid fever, according to the views advanced by Jobling[14] and by Teague and McWilliams.[15] However, careful research by Schamberg, Ringer, Raiziss and Kolmer[1] failed to determine any organism as the causative agent.

It may be, as assumed by Spiethoff,[10] Gottheil and Satenstein,[2] and others who have used the autoserum therapy, that the psoriatic foci are rendered more susceptible to medication, or that the skin is rendered less susceptible to local treatment allowing prolonged and stronger medication without producing a dermatitis. This seems probable from the clinical phenomena and results which were obtained.

CONCLUSIONS

1. Intravenous vaccines alone do not clear up the lesions of psoriasis, though they do lessen the induration and inflammatory reaction.
2. When used in conjunction with weak chrysarobin ointment, the lesions clear up rapidly.
3. Favorable results were obtained in chronic generalized cases resistant to other forms of treatment.
4. Chrysarobin dermatitis is prevented by the vaccine, and when present yields promptly.
5. The action of the vaccine is not fully understood, but it seems to lessen the sensitiveness of the skin to local medication, allowing uninterrupted treatment.

LARGE VESICAL CALCULUS

J. P. Browne, M.D., Plainfield, Ill.

Miss A., a rather thin, anemic girl, aged 16 years, consulted me last July as she was troubled with constipation. She gave a rather obscure history of pain in the bladder and lower abdominal region, especially when urinating or having a bowel movement.

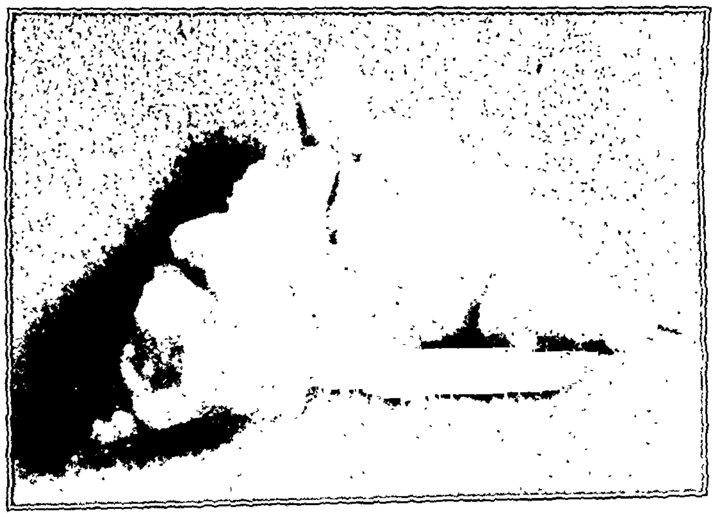
The patient stated that she thought there might be calculi in the bladder and that she had attempted to remove a small stone from the urethra with a hairpin.

A sound, when passed into the bladder, immediately struck a stone apparently at the bladder entrance to the urethra. An operation for removal of the stone was immediately advised, and the patient was removed to Silver Cross Hospital, Joliet, Ill.

A cystoscopic examination revealed the presence of a large stone with a foreign body embedded in it. Suprapubic incision for removal of the mass was determined on and immediately performed. An immense calculus 4 inches in length and 3 inches around several different circumferences was removed. The calculus had grown around a hairpin as a nucleus. The hairpin was lying in the bladder in a widely extended obtuse angle, and was covered with the deposit to within about a quarter of an inch of each end. The mass tapered from the center toward each point.

The bladder was thoroughly irrigated, the wound closed, and a retention catheter inserted. Daily irrigations were instituted, and an uneventful recovery followed.

The accompanying illustration shows the exact size of the calculus, although portions of it crumbled during removal. The length of time that the hairpin had been in the bladder could not be determined, but the enormous size of the calculus would indicate that it must have been there for months, perhaps years.



Vesical calculus formed around a hairpin as a nucleus.

Selective Gymnastics.—The director of hygiene of the Dayton, Ohio, schools has recommended to the school authorities a plan for gymnastic instruction of the school pupils on a selective plan. The children will be divided into groups after careful physical examination, and each group given such exercises as are adapted to their strength, requirements, etc.

Military Medicine and Surgery

THE WORK OF THE AMERICAN RED CROSS MISSION TO RUSSIA *

FRANK BILLINGS, M.D.
Chief of the American Red Cross Mission to Russia
CHICAGO

The mission that I had the honor to lead into Russia was composed of twenty-one commissioners; I have never been associated with a finer body of men. Those from Chicago, Major Wilbur E. Post, Major Harold H. Swift, and Major Raymond Robins, made me feel proud of Chicago. Each of those men was on tiptoe, as indeed was every other member of the mission. There are some members of that mission who need mention; but when I do mention some of their names it does not mean that the work of others on the mission was less notable. As it happened, because of conditions in Russia and because of the character of the men, Raymond Robins did a notable work and is continuing to do notable work there. If Chicago does not know Raymond Robins yet, I want to say that Chicago should cherish and honor Raymond Robins because if ever man did, he loves his fellow men.

All the men from the East did notable work, and some of us left this country without much sacrifice; but this was not true of all. One man whom I invited to go was with me in Russia twenty years ago. I knew that the one being on earth that made life worth living to him was an invalid, and that perhaps he could not go; but when his wife heard that he was invited to go she said to him and to his friends that she would be made absolutely happy if he would go, because she felt her illness of years had kept him from doing the things for his country that she desired him to do. And when they bade each other good-by, it was with the feeling that they would never see each other again. He left with the mission, and in August that patriotic woman died. Can you think of any more sublime patriotism than that expressed by this noble woman and by her husband, Dr. W. S. Thayer, who went with me to Russia? Dr. Thayer remains with the other members of the mission left in charge of the Red Cross work there, the chief of the medical department.

We were four months away from Chicago, and were two months in Russia. That is but a short time. It would, therefore, be presumptuous on the part of any one who would say that he brought a final word of Russia to you. Even those who have lived in Russia for years do not understand Russia; but because of the nature of our mission, and because of the problems put up to it by the War Council of the Red Cross and by Mr. Root, we made a broad survey of conditions in Russia, including an investigation into conditions that involved the revolutionary government, the sanitary department of her army, the public war relief organizations of Russia, food for the army, and many other problems related to the civilian population. This necessarily brought knowledge to the members of our mission that we otherwise would not have obtained, and it is because of this that I presume to tell you something of Russia tonight.

Fig. 1.—Lieut.-Col. Frank Billings, chairman of the mission.

POLITICAL CONDITIONS IN RUSSIA

To make you understand something of what we saw in Russia, I should like to give a perspective of that great nation. Those who have not been in Russia think of Russia as a big country, as it is; but you do not know how vast it is. One thinks of Siberia as a place that is barren, cold, inhospitable, and not fit for the habitation of man, and a place which Russia under the old régime has used as a prison house for its civilian and political prisoners. That is not true. Russia, including Siberia, is vast, and when one travels through it the distance from one point to another seems interminable. The Trans-Siberian Railroad extends 5,500 miles from Vladivostok to Petrograd. The territory in extent, as it existed before the war, is over 6,000 miles from east to west, and over 2,000 miles from Archangel to Odessa. This vast country is populated by only 180,000,000 people. I say only 180,000,000 because there is room for 500,000,000 and more. Siberia alone, with over 5,000,000 square miles, has only about 6,000,000 people, and these are mainly scattered along the Trans-Siberian Railroad, which traverses one of the most beautiful countries that man may look on. It is like traveling through our beautiful Western States. There are magnificent forests, vast in extent, beautiful lakes here and there, with a wonderfully fertile soil, as evidenced by the growing crops when we passed through it. We saw herds of cattle, of sheep and of swine everywhere.

As one met the people at the stations, soldiers and civilians, they were as fine looking a lot of manhood and womanhood as one could wish to see anywhere.

---

* Address delivered before Physicians Club of Chicago, Nov. 1, 1917.

Think of that vast country, with a vast population, as compared with ours, ruled for centuries by an autocratic power! When there was a czar more humane than others, a bureaucratic cabinet made him relatively as cruel as any other, and not only held this great people in bondage, but kept them illiterate for a purpose; kept them in serfdom for many years; did not let them think or act for themselves; and when we arrived in Russia these people, autocratically governed, had been at war for three long years with the most cruel nation the world has ever known. She had fought not the good fight that her allies expected of her, but nevertheless she had fought; and think of the long line that she attempted either to defend or from which to send an offensive over 1,200 miles of battlefront. She had placed millions of soldiers into the army. From the beginning there have been mobilized 16,000,000, and of this number 6,000,000 may be accounted for; 2,000,000 or more are prisoners in Germany and in Austria. A large proportion of the remaining 4,000,000 were killed; others are incapacitated for further service in the army either by wounds, by a crippled condition, or by invalidism. That leaves at the present time about 10,000,000 soldiers under arms. Of that number, about 3,000,000 are at the front covering 1,200 miles, and the remainder are in barracks all the way from the front to Siberia and down to the Crimea, so that everywhere in Russia at the present time one meets soldiers.

Fig. 2.—Major William S. Thayer, Baltimore.

In the midst of this war, during which there have been made disastrous advances and masterly retreats, her soldiers have been well fed and well clothed, but not always well munitioned or well armed. Many of them went to the front in the earliers years of the war without a musket, understanding then that they would become armed when they captured guns from the enemy or would secure them when their fellow soldiers fell. I have heard the officers say that these men fought the Germans with their bare hands during the first years of the war. They were good soldiers, and then in the midst of this terrible war, with the mismanagement of the old régime, with traitors in her cabinet, came a revolution almost in a night. One hundred and eighty millions of people, who had been held under autocratic sway, were told they were free to do what they pleased. Can you wonder that those people were more or less confused? They had known something of democracy, but not much. What they knew of democracy under autocratic rule they learned of themselves, for they established, away back in 1865, the zemstvo unions in their provinces. To the local zemstvos, delegates were elected by the peasants, and the central zemstvos in Moscow was represented by delegates elected by the local zemstvos. Through the zemstvos they established schools, cared for their sick and destitute, and learned better agricultural methods. When they advanced too far in that democratic movement and were improving too rapidly, the autocratic government stepped in and appointed a member of the cabinet in Petrograd and a member of the government in every province to modify and shape their activities.

THE PROVINCIAL GOVERNMENT

While they knew something of democracy gained from the zemstvos, it was colored with socialism, injected from the outside. Therefore, after the revolution there was established in Russia what may be called an experimental laboratory of socialism in the form of a provincial government. A cabinet was formed through the Duma, the fourth Duma. The Duma was the first legislative body that the people of Russia had ever enjoyed, and it formed a new cabinet because the extreme socialists, the Maximalists or Bolsheviki, and the Workmen's and Soldiers' Council,

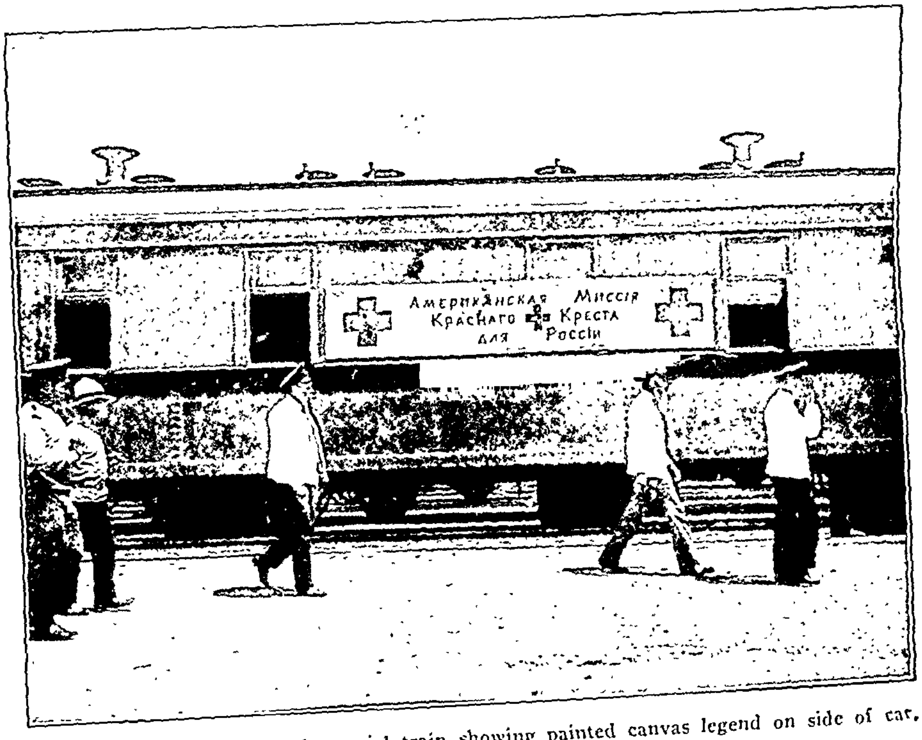


Fig. 3.—Car on mission's special train showing painted canvas legend on side of car, "American Red Cross Mission to Russia."

the representatives of the strongest socialists of Russia, did not care to take the responsibility of the first cabinet. Therefore, the Duma formed the first provisional cabinet. In that cabinet were some of the biggest men of Russia. Prince Lvov was the premier, Mr. Milyoukoff the foreign secretary, Mr. Routchkoff the minister of war, and Mr. Kerensky the minister of justice, all men of fine character. The other cabinet ministers were of less importance. Immediately after the cabinet was formed, the Duma legislated itself out of existence. The socialists demanded and obtained the abolition of the death penalty and of all discipline in the army. The minister of agriculture declared an agrarian policy which has been one of the most harmful things done in revolutionary Russia. He declared that the imperial lands, the lands of great estates, and even the lands held by eight or more million peasants should revert to the state and be divided among the people of Russia. They demanded that the war, if continued, should be fought without annexations and without indemnities. They ordered the minister of war to recognize committees in the army who should supersede the officers and decide military tactics and other conditions of the army, including its domestic functions. The men of character in the cabinet refused, and so the first cabinet lasted but a few weeks. That left Russia without any legal body to form a new cabinet, and in revolutionary Russia they soon came to a satisfactory method of doing this. The political parties, including this vast body of socialists, the greatest number in Petrograd, agreed to the formation of a coalition cabinet in which the socialists dominated. Neither of these three great men I have named could accept a place in the cabinet, and so the next one was formed of men of lesser importance, but with Mr. Kerensky, who was minister of justice at first, the minister of foreign affairs, and Mr. Terestchenko, who had been in the first cabinet, also in the new one. The people accepted the cabinet of this provisional government, which had been created without legal status. The second cabinet lasted only a little while, and so it has gone on until there have been six cabinets formed since the revolution. The last one was formed about the middle of September. Mr. Kerensky has been in each cabinet, and after the third cabinet he rose to the position of premier, and Mr. Terestchenko has occupied the next important place, that of foreign minister. I have taken time to say this, for if you do not understand the political conditions as they exist in Russia today, you cannot understand the spirit and the character of the people of that country, who not only recognize but support a government formed as I have attempted to describe.

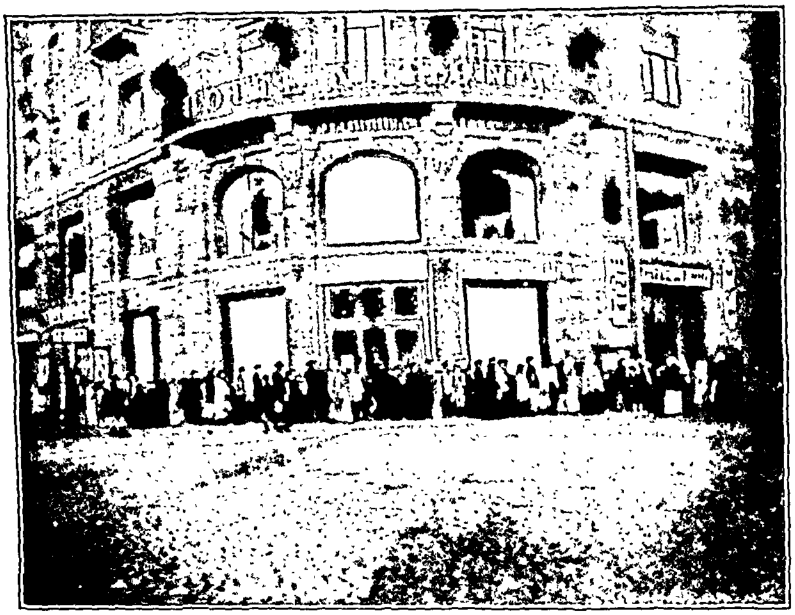

Fig. 4.—Bread line in Moscow.

The army under this revolutionary system became disorganized because of the abolition of the death penalty and of discipline, and because of the appointment within its own ranks of committees of soldiers who dictated to the officers what should be done. What could follow but disaster? In spite of all disorder, they have held the trenches; they made an unwise advance in Galicia last summer. At the Riga front some units fought well and others not at all. Disorganized and inefficient as they have been, still they have held twenty-two German corps at bay all summer, and they still hold them. Amid this disorder, sanitation was neglected. When sanitation is neglected infectious diseases and infestation with vermin increase, with the result that there were more sick soldiers than Russia had had since the war began. But in spite of these things the line holds.

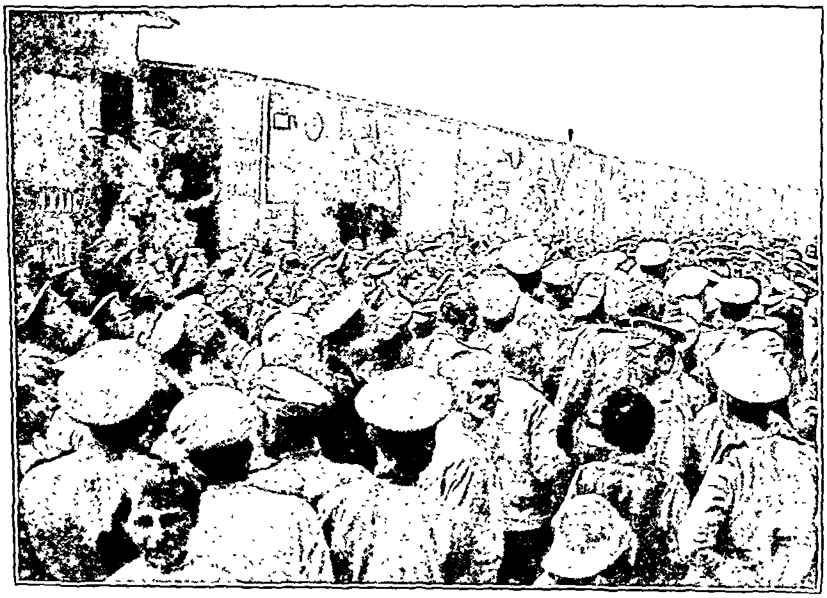

Fig. 5.—Crowd of Russian soldiers at one of the stations, showing a Russian troop train.

But what of the disorder in the rear as a result which must necessarily come? Even under the old régime there was mismanagement of her civil government. The productive industries, which began to decline during the old régime, after the revolution diminished more than ever. Strikes occurred after the revolution because the peasants and soldiers believed that liberty meant the right to be idle, just as our liberated slaves did after our war. The flour mills gave a diminished output; transportation was more or less crippled because the industries were diminished in productiveness and because of labor strikes. All of these factors led to a diminution in the value of the ruble.

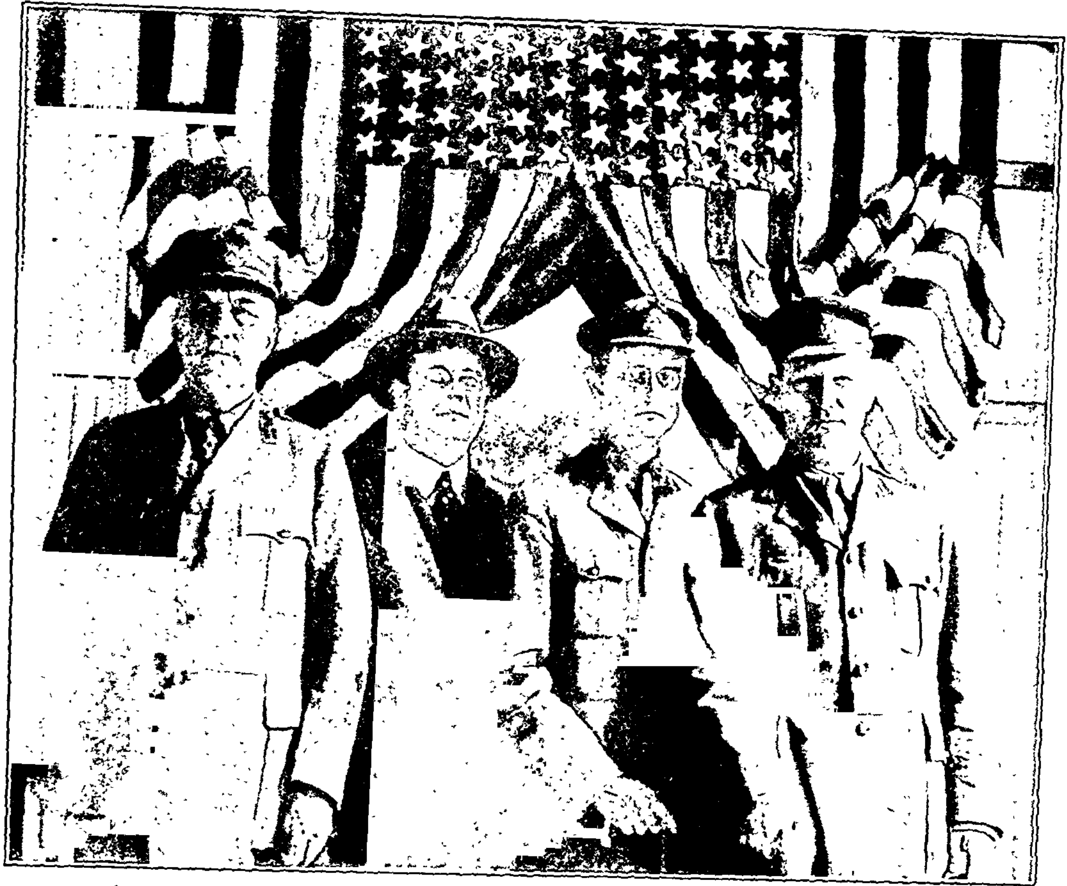

Fig. 6.—Group of Chicago members of the commission at the mission headquarters in Petrograd. From left to right: Lieut.-Col. Frank Billings, Mr. Samuel Harper, Majors H. H. Swift and Wilbur E. Post.

Mr. Root left a letter at Vladivostok in which he stated to our mission that the food problem in Russia was the crux of the situation; that if food scarcity continued in the large cities like Petrograd, Moscow, Kiev, and in certain provinces, riots would recur as they did in 1916-1917. With riots in the rear, great disorder would occur at the front; the soldiers would evacuate the trenches, and that would mean that a greater number of American lives may be sacrificed in France.

It did not take much investigation to show that if our mission did help in the food problem it would not be as a Red Cross mission, but as a diplomatic body.

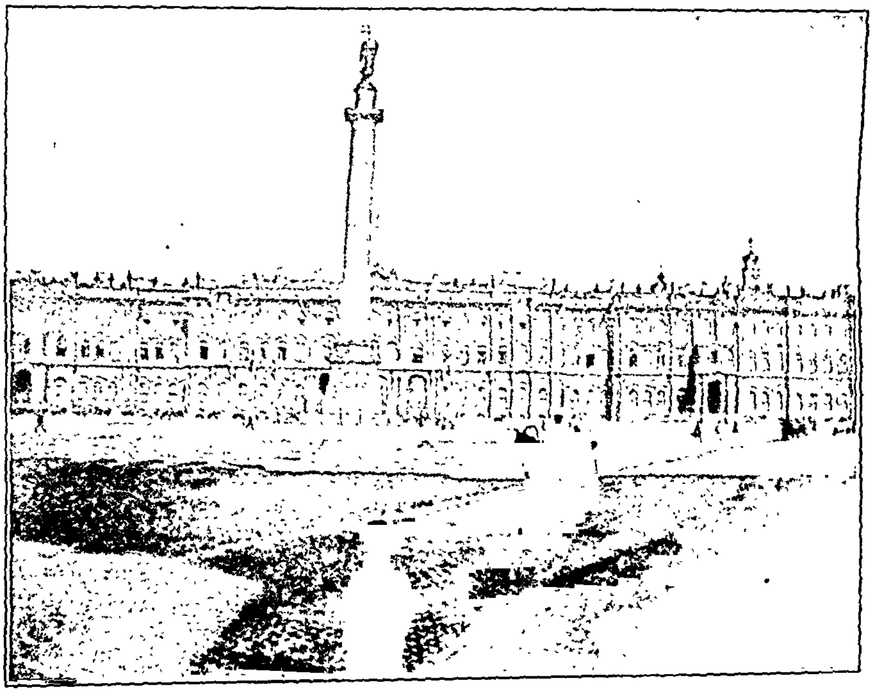

Fig. 7.—The Winter Palace in Petrograd, containing a Red Cross hospital of 500 beds, government offices, etc.

REASONS FOR A HOPEFUL OUTLOOK

I have told you some of the worst things of Russia. Let me tell you why I have come back very optimistic about Russia with this background, with this sort of perspective of that great nation. The provisional government of Russia, composed of men chiefly socialists, in the beginning was, as I have said, an experimental laboratory of socialism. The socialists the world over looked on that socialistic government as one that would be copied everywhere; that it would be eminently successful, and that Russia would be a very democratic government because based on socialistic ideas. This government has been in existence about seven months, and in that time those who were strong socialists in the early cabinets, those who believe in socialism as the bulwark of democracy, have learned a lesson. The result is that the cabinet of today in Russia is the strongest she has had since the revolution. Mr. Kerensky is a man only 34 years of age, a lawyer, who had never had any experience in administration or organization. He was a very extreme socialist, had been in every cabinet, and had been premier in four of the cabinets. It was through him that discipline in the army and the death penalty were abolished. Responsibility has brought a change in the man. He has restored the death penalty. I saw in one of the newspapers yesterday that the death penalty had not been restored. It has been restored because this was done while we were in Russia, and men who have refused to obey have been shot. He is gradually reestablishing discipline. Americans ask, Why does he not establish it at once and by force if necessary? Remember that the government was started by socialists, who were in the majority, and any attempt to suddenly bring back order in the army would have meant counterrevolutions. Disorder can be overcome only by the education of the people through bitter experience, and they are receiving that education. They have learned that socialism is not and cannot be the fundamental foundation of a democratic liberty. Mr. Kerensky has learned it so thoroughly that he has repudiated socialism, and the Bolsheviki have repudiated him.

Fig. 8.—Madam Brosko-Broskovskeia, grandmother of the Russian Revolution, seated with a company of Russian officers and soldiers.

KERENSKY

Mr. Kerensky is an honest man. He looks at one squarely; he talks to one frankly. He is quick and alert physically, and just as alert mentally. He is patriotic. When I saw Mr. Milyoukoff last, three days before we came away, I asked, "Is Mr. Kerensky honest?" He replied, "Yes." "Is he patriotic?" "Yes. He is so intensely patriotic that he would die tomorrow if by so doing he could save his country."

The members of the cabinet, the people of Russia of all classes, have learned the lesson by bitter experience, that liberty has its price. That the price is law, order, discipline, and submission to leadership.

I saw enough of these men of the cabinet, talked to them about what they were doing, to make me believe they are honest, patriotic, and that they will finally bring the people of Russia into a condition of order with the proper understanding of what democratic liberty means.

THE WAR RELIEF ORGANIZATIONS

What else did we see that is heartening? The war relief organizations of Russia are the most wonderful I have ever seen anywhere. The sanitary deparment is headed by a physician who is one of the most celebrated bacteriologists and hygienists of Russia. He is a man of fine character, and the men on the staff are of the same fine type. They have done very efficient work in this war under the old régime and under the revolution. Remember that Russia, like America, secured many things from Germany before the war. They received as many packages of drugs and chemicals marked "Made in Germany" as we did, and when the war came they were without them. You and I had looked on the Russians as incapable of making those things, and yet they have gone ahead and manufactured them. The sanitary department, which conducts a factory in Petrograd for making drugs, surgical supplies, artificial limbs, crutches and other necessary supplies for the medical department of the army, is splendidly administered. They do not have the materials sometimes with which to make things, but when they have them they make them well. The sanitary department of the army at the front does good work, with the Red Cross and zemstvo union in field and ambulance work and in base hospitals. The front is one place where the three great war relief organizations cooperate; back of the front the cooperation ceases. The sanitary department of the army has plenty of medical men, but does need help in certain supplies. Motor ambulances and possibly an American ambulance personnel, including sanitarians, are much needed by the army.

The Russian Red Cross during the old régime was supported chiefly by the royal family. At the time of the revolution that income ceased, and since that time it has received governmental aid. It is a big organization. It tried to attach the mission to it because we were sent by the American Red Cross; but as we were sent to the Russian people and to no single organization, we told them we would cooperate with the Russian people as represented in the Red Cross, the zemstvo union and the sanitary department of the army. The Red Cross is doing great work. It has enormous factories and enormous supplies; more than we have. Its supply house in Petrograd is an enormous structure comprising many buildings. Dr. Orden, head of the supply department, told us that there were 50,000,000 meters of surgical gauze on hand; that they had 5,000,000 suits of underclothing in stock. They lack some of the things that America may furnish. One of the finest sights in our experi-

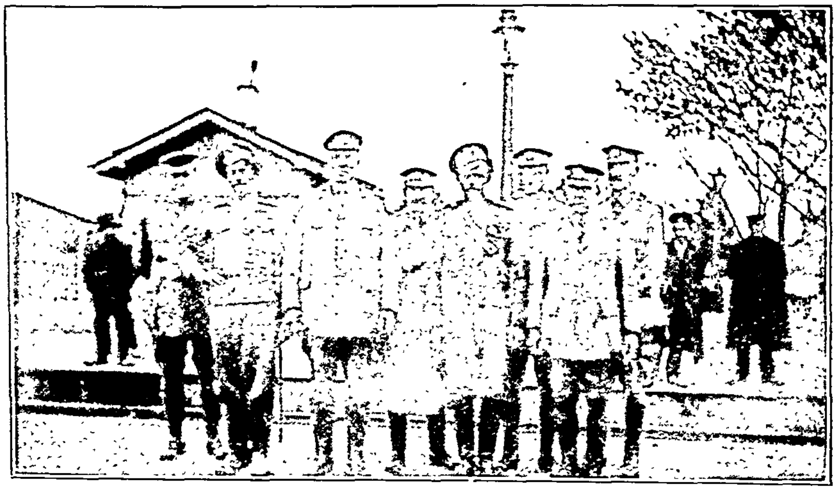

Fig. 9.—Group from the mission en route homeward through Siberia, including two Cossack guides. From left to right members of the mission are: Major W. E. Post, Chicago; Lieut.-Col. Frank Billings, Chicago; Majors H. C. Sherman, Columbia; H. H. Swift, Chicago; G. W. Whipple, Harvard, and C. E. A. Winslow, Yale.

ence we saw at Petrograd when we visited the Red Cross Hospital of 500 beds in the winter palace, the best use to which the winter palace was ever put. The winter palace is also notable at this time as the residence of the grandmother of the revolution, Madam Brosko-Broskovskeia. Under the old régime a political prisoner in Siberia, she now enjoys luxurious quarters in the palace while the ex-czar takes her place in Siberia. At Moscow the Red Cross had supply houses with hospitals equally as good.

THE ZEMSTVO UNION

But it is the great zemstvo union of which I want to say the most. The zemstvo union, as I mentioned a moment ago, with its branches in the provinces, has broadened its activities during this war. The old régime did not furnish the soldiers with sufficient clothing, boots, shoes, arms, or with munitions, so that the men were seriously handicapped. The zemstvo unions represented by millions of people, with the peasants as its fundamental basis, went to work and in 1915 and 1916 they tanned 500,000 raw hides to make boots and shoes for the soldiers at the front. They spun wool, and they made clothing for their soldiers. They furnished ambulances and field and base hospitals. They helped to furnish the evacuation hospitals together with the Red Cross and sanitary department of the army. During the war they have furnished 500,000 beds for the soldiers. Can you get that number? 500,000 beds! In Chicago we felt quite elated when we furnished four base hospital units of 2,000 beds all together. The Russian people have done an enormous amount of work, and have done it well. We had a committee visit the front. It found that the work was well done; but since the revolution there has been more or less embarrassment because of the lack of discipline among the soldiers, who refused to be inoculated with antitetanic toxin and also refused to be vaccinated as a preventive measure against cholera, typhoid and paratyphoid. The committee reported that the men were disregardful of sanitary measures at the front, but in spite of these things, the medical officers carry on their work and by persuasion have been able to do what they could not command the force to do. The three public war relief organizations operate 100 sanitary trains to and from the front. These are the evacuation trains that take the wounded and sick soldiers from the base hospitals to the rear. Russia is divided into seven evacuation districts, and of these the district of which Moscow is the center is the largest. In the Moscow district there are 200,000 beds, of which 20,000 are in Moscow. A meeting is held every day, and they know the number of soldiers coming from the front. When the wounded soldiers reach Moscow they are bathed and have their hair cut and their clothing is disinfected in a most modern way. Those who are sick and severely wounded are kept in Moscow hospitals, and those who have a lesser degree of wounds or illnesses are evacuated to the rear within two or three days. During the war the Moscow district has taken care of sick and wounded soldiers to the number of 2,700,000. Other districts have taken care of the remainder, a total approximately of 4,000,000 wounded and sick soldiers.

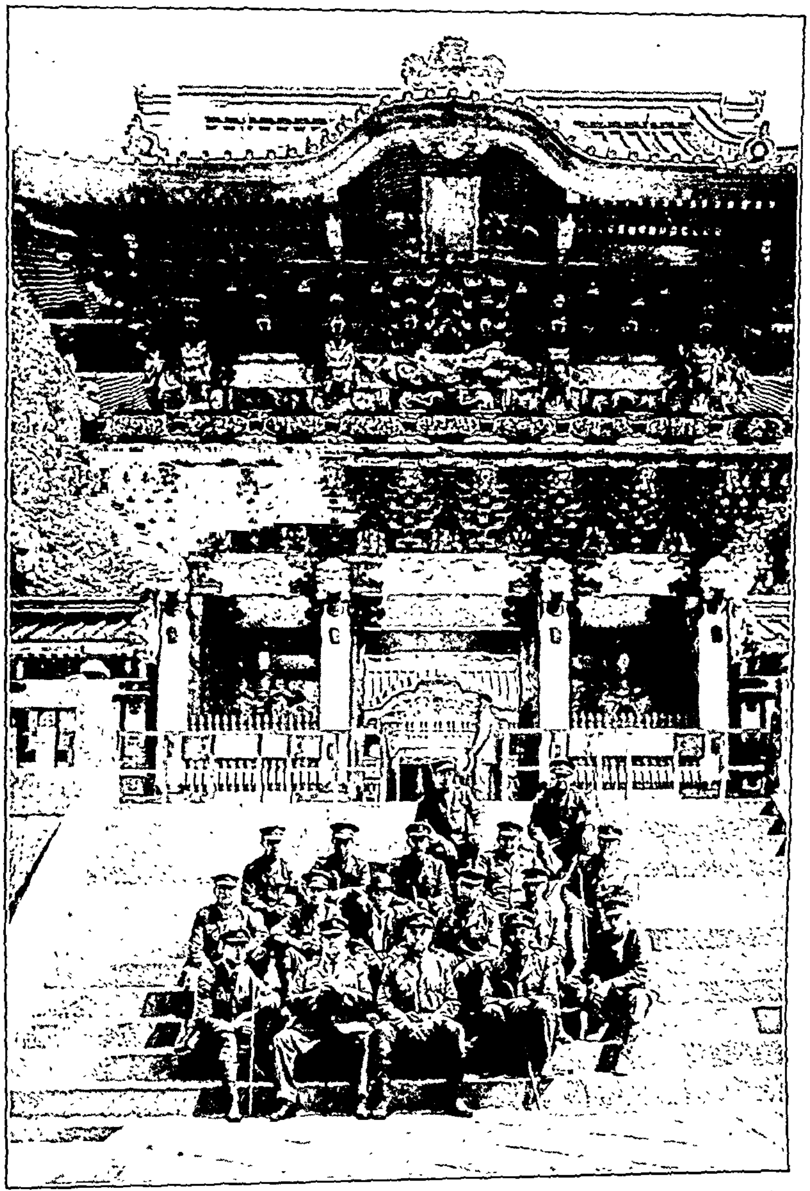

Fig. 10—Members of the American Red Cross Mission to Russia at Nikko, Japan.

THE CHARACTER OF THE RUSSIAN PEOPLE

The real substantial hope in Russia is the character of her people. In spite of the fact that the Russian people as a whole are illiterate, they possess characteristics that are so admirable, that it sets them apart from all other people that we have ever known. They are orderly, good natured, good hearted and industrious. They are the most wonderful technicians the world has ever known. The untutored peasant spins, weaves, tans leather, makes boots and shoes, and makes munitions. He will make a house with an ax and some wood. In spite of a long war, in spite of the revolutionary conditions, in spite of the absence of all police power and in spite of the erroneous ideas of liberty, there has been less disorder since July 4, 1917, the date of the last Petrograd riots, than there is in America today. When one travels, as some of us did, from Siberia to Moscow, and Petrograd to Archangel, to Odessa, to the front, and to various other places, we could not help but be impressed with the good order of these people. Sometimes soldiers would come into occupied compartments on the train, but they would not create any disturbance other than to impose their presence on one, as a harmless expression of their understanding of democratic liberty. I saw—and I know I speak for the other members of the mission—less disorder in Russia in two months among its civilian population than I may see in Chicago in any week in the year.

There is food scarcity in Petrograd, Moscow and in a few provinces. This scarcity in certain places is due to faulty distribution of food. Siberia, Southern Russia and Bessarabia have an abundance of food. Faulty distribution of food is due to lack of efficient river and railroad transportation. There was a like food scarcity in Petrograd and Moscow in 1916-1917 during the old régime. There is a lack of food and a lack of clothing, boots and shoes and many things the Russian citizens need. This is illustrated by the fact that each one must have a card and stand in line to secure supplies. The Russian accepts this quietly and good naturedly, never making a protest, never trying to get ahead of his neighbor and, if necessary, lying on the sidewalk all night that he may obtain the needed articles early the next day. He is perfectly satisfied if he finally gets the food and other things that his card calls for. Can you imagine a group of Americans lying on the sidewalk with cards to secure food, not trying to get ahead of their neighbors and not protesting to those in authority about it?

When we arrived at Vladivostok we were given the same train that the Root mission had used to come out of Russia. It is one of the imperial trains, with a combination diner and observation car—the same car in which the late czar, by a stroke of the pen, became Nicholas Romanoff. It is a beautiful train, but not so comfortable as many of our Pullman trains. We had plenty of food on the train, so that we went into Russia in a luxurious way. When we reached the larger towns and stopped for half an hour, the soldiers would read the Red Cross placards with legends in Russian on the windows, and received us with great enthusiasm. The Russians are great orators; so we would have two or three short speeches at every station, and always had to make replies to them.

When we reached Irkutsk, the capital of Siberia, there were a dozen or more freight trains loaded with soldiers mustered in from that region, going to the front. We ran in between them. We saw them bidding good-by to their wives and sweethearts, buying black bread and raw cucumbers, eating and singing. They greeted us enthusiastically, and made speeches. As we moved out of that station they came out of the freight cars and cheered us heartily. I said to myself: Fancy a Russian mission going to Washington and halting at some town en route and having a lot of our soldiers in freight cars halted in the same station. How many of our boys would cheer them? That is the spirit of the Russian soldier; that is the spirit of the Russian people.

THE COSSACKS

In addition to the spirit manifested by the people of Russia, one of the most important factors stimulating one's optimism of Russia's future activities in the war is the fact that, taken as a whole, the Cossacks are patriotic, democratic, submit to discipline and are excellent fighters. It is difficult to make an estimate of the number of Cossacks in the Russian army. It was named as from one to three millions and the minimum is certainly one and one-half million men.

CHEVALIERS OF ST. GEORGE

In addition to the Cossacks there is a society known as the Chevaliers of St. George. This numbers eight hundred thousand men. The members of the society have been decorated with the order of St. George for some act of bravery or other service to the country since the war began. The members of the mission met many groups of the Chevaliers of St. George and found them desirous of the reestablishment of law and order and of discipline in the army. They asserted many times that they would fight to the last. Always on the battle front there have been units of soldiers, sometimes large, sometimes small, who have fought well, while others failed in the offensive. These loyal units are usually composed of Cossacks and of the Chevaliers of St. George. We may count, therefore, on not less than two to three millions of loyal troops in Russia who will submit to discipline and who will fight.

TALK OF PEACE

In Russia today you hear no word, excepting from pacifists, excepting from the paid agents of Germany, and there are many of them, of a separate peace. It is believed by the present leaders in Russia that Russia will have an organized army by spring, and they say that she will never lay down her arms to an autocratic Germany. The trouble is that Russia is isolated. In Russia we were as much isolated in one sense of the word as if we had been on an uninhabited island. There is no news of America in Russia except what comes through German sources. In the Russian newspapers it is sometimes printed that America is in this war for sordid gain. In one paper I saw it stated that America was the vassal of England, and that England wanted to dominate the world. That is the sort of news they get about America. There is no news of the fine young men of our country who have registered, no news of conscription, no news of our numerous training camps, no news of the vast sums of money to carry on this war, and even no statement of the wonderful documents that have been issued by our great President. Can you wonder, therfore, that the Russians, who do not receive kindly attention or any information from our country that is authentic, feel themselves isolated as if they had to fight their battles alone? If you could have seen the expression on the faces of the officers of the relief organizations when we took the lists of our supplies to them, it would have thrilled all of you. They looked at the lists of supplies and said with a smile, "What is the price of this?" "How much more can we get of this or that," and "What is the price?" When we told them there was no expense, that this was a gift of the American people through its Red Cross to the people of Russia, the tears came into their eyes. It was the first time, in all probability, small as it was, that any nation has ever given Russia anything. Our allies do not understand Russia. They have not helped her as they should. They have not helped her in the materials she needs. She needs financial aid. They have not helped her in that spirit in which a great democracy should help a sister republic in its infancy.

AMERICA'S DUTY TO RUSSIA

Russia feels kindly toward America. She looks on us as her best friend. For what the Root commission has done, for what Mr. Stevens of the railroad commission has done, and for what we have done through our humble mission there, Russia feels grateful. She feels she has our friendship and she asks for more, but not greedily and not for very much. For certain things she desires to pay. This is America's opportunity. If America will help Russia at this time not only with money, but with the means whereby she can start a Russian propaganda to obtain news from America as the other allies are doing, great good will be accomplished. I am happy to say to you that we have already started that propaganda through the generosity of Col. W. B. Thompson, vice chairman of the mission. It was put before our President, and he has accepted it and has further agreed that it will be supported until Russia has adequate information of what is going on in America, and that America is her friend.

I want to repeat: I have come back full of optimism about Russia. She is doing a great work. She has a large army that must be properly cared for. She has a lot of fine men, even though they are socialists; they are intensely patriotic, and are learning to be rational through the responsibility that has come to them as members of the government. We owe to them our help to form a stable democracy, and we can do it. If we do that, we shall save American lives in France; if we do that, we shall finally cement the friendship of Russia, which is already ours.

DEVICES FOR THE SANITATION OF TRENCHES

SIMON BARUCH, M.D.

NEW YORK

Any enhancement of the comfort, hygienic condition and safety of our defenders merits speedy attention. For this reason I venture to suggest some devices that presented themselves to me while reading the description of trench sanitation by Dr. C. C. McCulloch.[1]

McCulloch writes: "It naturally adds much to the efficiency of this system if the urine can be handled separately, particularly in incinerator methods. This is done in some cases by separate urine buckets, in others . . . by urine soakage pits."

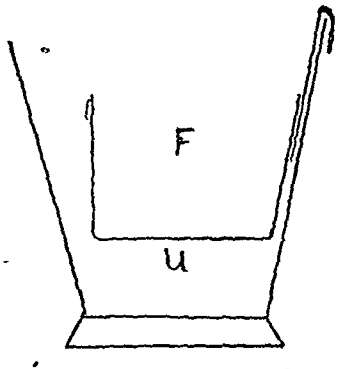

Fig. 1.—Emergency bucket, used in early trench construction: *F*, feces; *U*, urine.

Plan 1.—A method of separating the liquid from the solid excreta is illustrated in Figure 1 as applicable to the bucket now in use according to McCulloch's illustrations.

A separate bucket for the solids is suspended by a strong flange from the posterior upper rim of the large bucket now in use. It will be noted that the anterior rim of the feces bucket is flattened to increase the space for urinating. The urine flows downward and is thus separated completely.

The entire apparatus may be carried to the disposal pit, as indicated in McCulloch's Figure 3. The solids may be dumped into the pit and the fluid poured anywhere that the sanitary officer may direct.

Plan 2.—A better apparatus may be made (Fig. 2) of a strong metal bucket the size of that now in use, with metal seat and hinged lid.

Mr. Penfrase of the J. L. Mott Iron Works suggests that a pressed steel bucket would be more economical, because lighter and more durable than galvanized iron.

The advantage of this metal arrangement is obvious. Even the cost, if this deserves to be considered when the welfare of our boys is to be promoted, must be less. Transportation and sanitary conditions also are improved by avoiding wood. This applies to the succeeding devices.

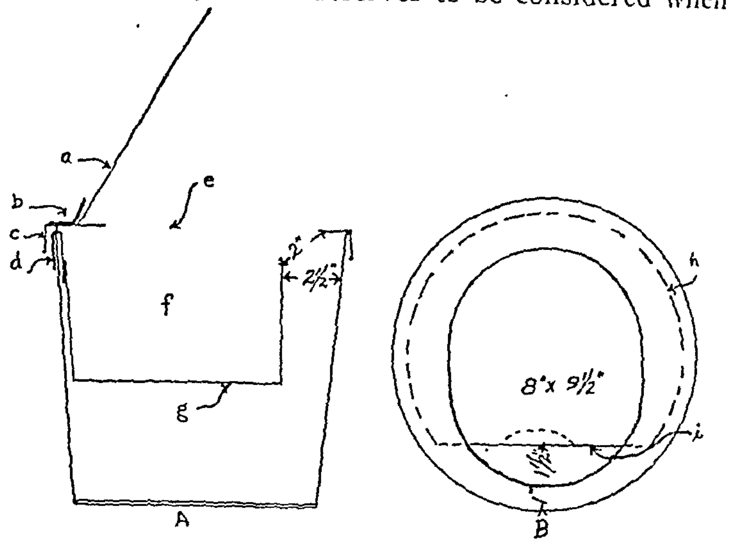

Fig. 2.—Metal bucket: *A*, section; *B*, top section; *a*, hinged cover; *b*, stop to make cover self closing; *c*, detachable cover; *d*, support holding feces bucket; *e*, opening, 8 by 9½ inches; *f*, feces bucket, with a capacity of 1½ gallons; *g*, urinal, with a capacity of 2 gallons; *h*, cover of bucket; *i*, front of feces bucket.

The foregoing buckets may readily be conveyed to the trenches when they are first constructed. When, however, the trenches are fairly well established, the following devices present advantages that appear to me obvious.

Plan 3.—Noting in McCulloch's diagram (Fig. 1) showing arrangements for food, water and the handling of excreta that under "conservancy" the buckets are placed in close proximity to the urine pits, it occurs to me that Figure 3*A* presents an ideal plan. It shows a septum with sufficient space for urinating, leaving the entire posterior compartment for the solids. The urinal portion terminates in a tube sufficiently long to fit loosely in a wooden, earthware or galvanized iron box or in one of the cones illustrated in Figure 4 of McCulloch's article rising from the urine pit.

The bucket and covers now in use may be continued with the exception of the added urinal septum, which is easily soldered on or riveted to the anterior part of the bucket. In this plan, the urine soakage pit must obviously be made larger.

So far I have suggested the continuation of the buckets now in use. I venture to add the following for the careful study of our military hygienists:

Plan 4.—When the bucket is carried to the disposal pit, the wooden fly proof cover may be left in the trenches, if the feces are covered by a cardboard shaped to the bucket. This would prevent odor and access to flies. A rack for holding a supply of these light covers is provided on the frame support.

A still greater improvement would be to place a waterproof paper container within the feces bucket. This would obviate the disagreeable and unwholesome scraping and cleansing of the bucket after the mass has been dumped into the disposal pit, and save its wearing.

---

[1] McCulloch, C. C.: Sanitation in the Trenches, The Journal A. M. A., July 14, 1917, p. 81; July 21, 1917, p. 183.

Before removal, the solid excreta are covered with the cardboard cover, and other refuse of light character is thrown on it to fill the bucket. The bucket, now holding at least threefold more material than in the method illustrated in McCulloch's Figure 3, may be conveyed just as readily to the disposal pit and there dumped for incineration, etc.

Care must be taken not to break off the tube at the lower end of the urinal compartment. It should be made strong, rectangular, and should fit loosely into the urine soakage pit entrance.

Plan 5.—For trenches that are being occupied for long periods, as now in Flanders, the following arrangement offers obvious advantages:

As indicated in Figure 3*B*, the urinal portion is made separate, and is secured to the corner supports of the frame anteriorly. The feces bucket is flattened to have its anterior wall correspond to the shape of the posterior wall of the urinal. For additional security and prevention of spilling between the two walls, a flange is cut in the anterior wall of the septum to fit firmly but loosely over the posterior cut out wall of the urinal. The latter is so arranged that it terminates in a strong tube. In this plan the feces bucket alone is removed, the feces being covered with a paper or metal lid. If the bucket has been lined with paper, the arrangement is obviously ideal.

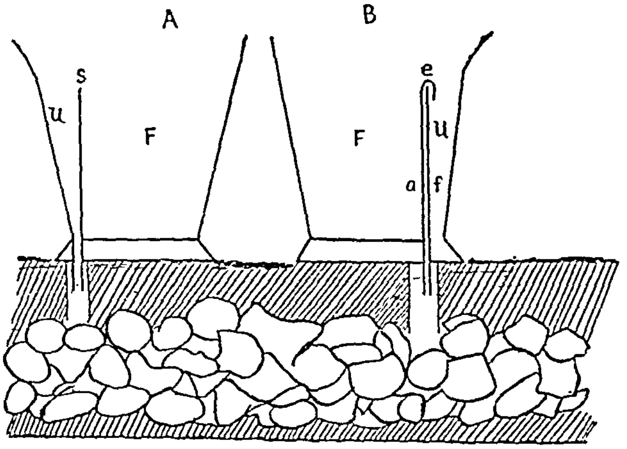

Fig. 3.—Permanent bucket, used in established trench construction: *F*, feces bucket; *U*, urinal; *s*, septum forming a urine conduit anteriorly; in *B*, separate urinal is secured to frame, and feces bucket is united to it by a flange; *e*, anterior part of feces bucket hooked on posterior portions of stationary urinal; *a*, anterior wall of feces bucket; *f*, posterior wall of separate stationary urinal.

In Plans 4 and 5 the feces bucket has its capacity increased about 33 per cent., which means less frequent emptying, and consequently less exposure to the enemy's fire, less labor, and more comfort for all concerned. The base under the bucket, shown in Figure 2 of McCulloch's article, is omitted in my device, in order to facilitate transportation in large quantities by sliding the bucket into the preceding one, forming nests.

The man behind the gun is made more efficient and more safe, the chief considerations.

Health a Community Asset.—Health is not the property of the individual who enjoys it, but of the community; disease menaces not only the sufferer, but all with whom he may come in contact.—Bertha Ott, *Public Health News* (N. J.).

New and Nonofficial Remedies

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application. W. A. Puckner, Secretary.

SILVER PROTEIN COMPOUNDS

Silver protein compounds possess the antiseptic action of silver nitrate to some degree. They do not precipitate proteins and are relatively or entirely nonirritant. They are frequently used as substitutes for silver nitrate, especially for the prophylaxis and treatment of the sensitive mucous membranes, particularly in gonorrhea, conjunctivitis and other infections of the urethra and of the eye, ear, nose and throat.

To prepare solutions of silver protein compounds the substance is sprinkled on distilled water and allowed to dissolve; in this way the formation of lumps, which dissolve slowly, is avoided.

SILVER PROTEIN-SQUIBB.—A compound of silver and gelatin, containing 19 to 23 per cent. of silver in organic combination.

Actions and Uses.—See general article on Silver Compounds, under Silver Protein Compounds.

Dosage.—Silver protein-Squibb is used in solutions containing 1 to 25 per cent., or more. It is also used in the form of bougies or suppositories.

Manufactured by E. R. Squibb and Sons, New York. No U. S. patent or trademark.

Silver protein-Squibb is produced by the interaction of silver oxide and gelatin in the presence of an alkali at a temperature of 80 to 100 C. When combination has occurred, the solution is concentrated in vacuo and the product sealed.

Silver protein-Squibb occurs in the form of black, lustrous, odorless, non-hygroscopic scales. It is very soluble in distilled water; insoluble in oils and alcohol.

No precipitate is produced when sodium chloride solution is added to an aqueous solution of silver protein-Squibb. An aqueous solution of silver protein-Squibb does not coagulate albumin; it is decomposed with precipitation by addition of free acids; ferric chloride decolorizes the solution.

Place about 0.5 Gm. silver protein-Squibb, weighed accurately, in a Kjeldahl flask together with 10 Gm. potassium sulphate and 10 Cc. of strong sulphuric acid and heat until the contents are colorless or only faintly yellow and allow to cool. Dilute the contents of the flask to about 100 Cc. with water, add ferric ammonium sulphate *test solution* as indicator and titrate with tenth-normal potassium sulphocyanate volumetric solution. The silver content corresponds to not less than 19 per cent. nor more than 23 per cent. of metallic silver (1 Cc. tenth-normal potassium sulphocyanate is equivalent to 0.010788 Gm. Ag).

ARSENPHENOL-AMINE HYDROCHLORIDE.—Arsenphenol-Aminae Hydrochloridum.—$HCl.NH_2.OH.C_6H_3As:As.C_6H_3.OH.NH_2HCl+2H_2O$.—The hydrochloride of 3-diamino-4-dihydroxy-1-arsenobenzene, corresponding to 31.57 per cent. arsenic (As).

Actions, Uses and Dosage.—The same as those of salvarsan (see New and Nonofficial Remedies, 1917, p. 45).

Arsenobenzol (Dermatological Research Laboratories).—A brand of arsenphenol-amine hydrochloride.

Manufactured by the Dermatological Research Laboratories, Philadelphia Polyclinic, Philadelphia, Pa. (General Drug Company, New York City). No U. S. patent or trademark.

Arsenobenzol (Dermatological Research Laboratories), 0.6 Gm. Ampules.—Each hermetically sealed ampule contains 0.6 Gm.

ACETYLSALICYLIC ACID (See N. N. R., 1917, p. 265).

Acetylsalicylic Acid-Milliken.—A non-proprietary brand complying with the standards for acetylsalicylic acid. Sold only in the form of capsules and tablets (see below).

Acetylsalicylic Acid-Milliken Capsules, 5 Gr.—Each capsule contains acetylsalicylic acid-Milliken 5 grains.

Acetylsalicylic Acid-Milliken Tablets, 5 Gr.—Each tablet contains acetylsalicylic acid-Milliken 5 grains.

Manufactured by Jno. T. Milliken & Co., St. Louis.

Acetylsalicylic Acid (Aspirin), Monsanto.—A non-proprietary brand complying with the standards for acetylsalicylic acid.

Manufactured by Monsanto Chemical Works, St. Louis.

THE ALLEGED FORMATION OF CONNECTIVE TISSUE FIBERS FROM FIBRIN

In the progress of scientific theories it is not uncommon to find opinion swinging alternately back and forth between two seemingly conflicting views, until a sufficient accumulation of facts finally permits an incontrovertible judgment to be formed. Something of this sort seems to be going on in relation to a debated feature of wound healing. The generally prevailing view, as was pointed out some time ago in The Journal,[1] has been that the fibrin, in wounds healing by first intention, forms a temporary tissue which holds the wound surfaces in place and stops up the wound, thus preventing infection. Later the fibrin disappears, not by liquefaction, but through an actual consumption by the new tissue cells, which show a positive chemotropism to the fibrin mass and are thus attracted into the fibrin clot in large numbers. The permanent tissues that go to fill the wound space are then formed by these cells through an intracellular action.

Baitsell[2] of Yale University has observed that a fibrin clot formed from plasma, under conditions in which the now familiar "tissue cultures" are carried out, may be transformed into a fibrous tissue which resembles connective tissue. Sometimes the plasma clot surrounding the embedded living tissue became almost completely transformed, by a fusion and consolidation of the fibrin elements, into the new fibrous tissue. Similarly, in experimental wounds on frogs there was a coagulation tissue formed by the clotting of the blood and lymph, and in this a typical fibrin net was present. Later this fibrin net was directly transformed into a new fibrous tissue containing bundles of wavy fibers as noted above. In fact, this process was found to be identical with that which had been previously found to take place in the fibrin clots in living cultures of adult frog tissues.

Lambert,[3] while admitting that in their physical character the newly formed fibrils resemble the collagen fibrils of true connective tissue, believes that the resemblance is a superficial one and that it is not of importance in a differential study. The question of the participation of connective tissue cells in the genesis of such fibrils in healing wounds is at issue. In new experiments in which living tissue has been completely excluded, Baitsell[4] has now shown the formation of a fibrous tissue from a plasma clot in direct response to the influence of purely mechanical factors of various kinds. The experiments have eliminated all possibility of the new fibrous tissue's being formed by cellular action. The structure of the new fibrous tissue as shown by a histologic study of the prepared material closely resembles that of regular connective tissue.

The fact, says Baitsell, that the new fibrous tissue is similarly formed in wounds, that is, by a direct transformation of the fibrin clot, where it functions as a regular connective tissue for a time at least, gives clear evidence that the transformation of the plasma clot is not an artefact, which occurs merely in tissue cultures and in clots that have been subjected to various external influences, but is a reaction which evidently plays an important part in wound healing in the frog. We have no conclusive evidence at present that the transformation of the plasma clot into the new fibrous tissue is more than a radical morphologic change. It is difficult to see how a chemical transformation of the protein fibrin net into a collagenous connective tissue could be brought about, and consequently there is the possibility that the new fibrous tissue serves only temporarily as a connective tissue and is later replaced by a permanent tissue formed by a cellular action of some sort. On *a priori* grounds, however, there would appear to be no good reason for supposing that a tissue such as the new fibrous tissue, which is typical in its structure and which functions normally in wounds, would ever be replaced by another tissue.

The observation that the extent of this transformation of a fibrin-containing clot can be controlled by such purely mechanical factors as tension or pressure, so that filaments or rods of fibrin change to wavy fibrillae which unite to form heavy fibrous bundles, is not explained by the theory of the intracellular origin of connective tissue fibers. The chemist might be of assistance here in explaining the seeming contradiction of forming one kind of albuminous structure out of a totally different one. Baitsell is convinced that morphologically, at least, the fibrin net can by fusion and consolidation be converted into a fibrous tissue which in its morphologic structure, to say the least, is apparently identical with normal connective tissue of the frog. He even suggests that in response to various mechanical factors a reaction of this kind may play an important part in the formation of the connective and supporting tissues in the development of the individual. Reserving final decision, we shall await the further contributions to this important subject with interest.

THE SOLDIERS' AND SAILORS' INSURANCE LAW

What will become of the kiddies and their mother if I am killed? What will become of them and me if I am permanently disabled? As between my country and my dependent family, where does my duty lie at this stage of the present emergency? These are questions that have bothered many of the medical men and others who have responded to the call to the colors, and the absence of a satisfactory answer has prevented a considerable number from responding. The soldiers' and sailors' insurance act, passed by Congress, Oct. 6, 1917, and the regulations promulgated, October 15, under authority of that act, concerning governmental insurance, will encourage those who have already entered the service, and will doubtless impel many to enter who have been in doubt as to the line of duty.

The act guarantees to every medical officer (or in event of his death then to his wife, children and dependent mother, if there be any), certain stated compensation, during the disability of the officer, or during the dependency of the widow, children or widowed mother, as the case may be. During such disability the disabled officer will be entitled also to medical, surgical and hospital services, with necessary supplies, at government expense. And should his disability be such as to prevent him from following his profession, provision will be made for his education and training at the cost of the government in some available means of livelihood, so far as may be practicable, with the express provision that individual success in adapting oneself to such a means of livelihood shall not result in a reduction in the amount of the money compensation or in the medical care to which the disabled officer is entitled.

The protection described in the preceding paragraph belongs to every medical officer and to the dependents named, as a matter of right; but if he desires to be further fortified against disaster, he may accomplish that result through the system of governmental insurance that the act establishes. Nominally such insurance is at the expense of the insured; but as the rates of insurance are computed merely on a peace basis, the government assuming all of the added risk arising out of the war, and as the government assumes all of the expenses incident to administration of the insurance system, the insured will obtain protection at a low rate. As all policies are convertible at the close of the war, without medical examination, into insurance policies of ordinary standard types, premiums paid for protection during the war will not be lost. Ordinarily application for insurance must be made within 120 days after entering the service; but men in the service, April 6, 1917, are by the terms of the act automatically insured up to and including Feb. 12, 1918, by which date they must have applied for such insurance as they desire, in the usual manner. Application can be made, however, before the latter date, in which event the insured will have the benefit of such insurance as he may select in lieu of the standard ad interim insurance named in the act.

The existence of such compensation as the law provides in all cases of death and disability, and the possibility of greatly adding by voluntary insurance to the protection thus afforded, should materially increase the number of physicians offering themselves for military duty, and should inspire all with a keener appreciation of the fact that the government has, after all, a sympathetic understanding of the needs of its fighting forces, and may be depended on to supply such needs.

PITUITARY FUNCTIONS

Broadly speaking, there are two ways in which the possible function of glands or organs of the body can profitably be studied. One of these consists in examining the physiologic properties of extracts of the tissue under consideration from the standpoint of discovering some "active principle" or potent constituent with which its normal performance may be linked. In the case of the thyroid, for example, this plan has been partially successful. The administration of thyroid-parathyroid products can produce results in certain abnormal conditions of the organism, such as cretinism, that lead to definite convictions regarding at least some of the functions of the thyroid apparatus. However, it must be frankly admitted that the evidence regarding even the vague details of precisely what the thyroid extract therapy accomplishes in such instances is at present nothing more than a matter of conjecture. The study of the suprarenals seems to have been more successful from the standpoint of studying the potency of its constituents and its secretion into the blood. Epinephrin has established a place in physiology, pharmacology and therapy. The ablation of the suprarenal glands which produce it is followed by death. Nevertheless the recent investigations of Stewart and Rogoff[1] of Cleveland must awaken considerable doubt as to whether epinephrin itself is essential for the continuance of life.

The second method of investigation referred to consists in partial or complete removal of an organ under investigation, and observation of the effects of this procedure. This scheme has given decisive answers in the case of a number of structures in the body. The indispensability of the parathyroid, pancreas or suprarenals, in contrast with the spleen or salivary glands, has thus been demonstrated. By extirpation experiments, much light has also been thrown on the relation of the sex glands to the development of secondary sexual characters. Yet the apparent negative results of many ablation experiments, as found in the study of the thyroid proper and the thymus,[2] for example, tend to awaken the belief that compensatory functioning in other parts may often obscure the real contribution of specific glands to the body's physiology after their extirpation or some damage to them.

---

[1] Is Epinephrin Indispensable for the Organism? editorial, The Journal A. M. A., July 7, 1917, p. 40.

Although no single method of study has been entirely satisfactory in elucidating the complete story of glandular function, the operative removal of isolated structures has thrown a flood of light into many obscure places in physiology. Pathologic anatomy, the outcome of Nature's experiments in disease, has often supplemented the extirpation experiment or pointed the way to its meaning. All of this is brilliantly exemplified in the modern study of the pituitary body. Although some of the details of the results of experimental interference have been in dispute, the major features are at length confirmed. Following the lead of Paulesco, professor of physiology at Bucharest, who introduced the most successful method of accomplishing experimental surgical interference with the pituitary body, and of Harvey Cushing and his fellow workers in this country, Blair Bell[3] has added testimony that should help to complete the story in some of its most important aspects.

Before referring to the results of this English worker, it may be well to remind the reader that the pituitary body consists of two clearly differentiated parts which have separate modes of origin. The anterior lobe is distinctly glandular in character; the posterior lobe is developed from the nervous tissue with which it is more directly connected. There is no longer any doubt that complete loss of the pituitary body is speedily followed by death which cannot be attributed to mere shock; it is therefore an organ that is essential to life. All the investigators are now further agreed that neither partial nor complete removal of the posterior lobe causes any symptoms. The genital organs, the development of which seemed to be correlated in some way with the integrity of the pituitary, remain normal after ablation of the pars posterior, and young animals continue to develop after such an operation. Hence the secretion of the pars nervosa is, to quote Blair Bell, neither beneficial nor essential to life. Bell finds that partial removal of both anterior and posterior lobes likewise causes no symptoms, provided only a small portion of the pars anterior be removed. On the other hand, the removal of very large portions of the pars anterior is incompatible with life. Bell regards it as convincingly demonstrated now that it is the loss of this portion of the organ that proves fatal when total extirpation of the pituitary is practiced.

Cushing and his colleagues have discovered that when the anterior lobe is partially removed in young animals a condition of persistent infantilism with absence of sexual development is likely to occur. Bell has likewise noted genital atrophy under such conditions. The manifestations of dystrophia adiposogenitalis, which Cushing has described in animals after interference with the anterior lobe, could be produced by Bell in only one way, namely, by interference with or separation of the infundibular stalk. This apparently brings about a disturbance of the blood supply to the gland. As a result there is an insufficiency of the anterior lobe. The cells of this part become shrunken, atrophic and discrete—a state of affairs which, as Bell says, is always found in the human subject afflicted with the syndrome of dystrophia adiposogenitalis.

It has been held by histologic students of the pituitary that a secretion from the posterior lobe which is in close juxtaposition to the nervous tissues passes directly into the third ventricle. But Bell points out that the only real secretory cells of the posterior lobe—the cells of the pars intermedia—are derived from the same source as those of the pars anterior. Removal of the posterior pars proper does not remove true secretory cells. Separation of the stalk interferes with the blood supply of all these cells. It is henceforth necessary, says Bell, to look on the functions of the pituitary as a whole, and to consider this structure as one organ and not two. The fortuitous juxtaposition of the epithelial cells and the pars nervosa, he adds, has probably no relation to the vital functions with which the pituitary is concerned. Even if secretion from the pars nervosa does pass into the cerebrospinal fluid, as has been asserted, Bell believes there is not the slightest evidence to show that this is essential, beneficial or even the normal method by which the internal secretion is taken up by the animal economy. The blood stream is the real path for the distribution of the pituitary hormone.

Tumors in the neighborhood of the sella turcica may be imitated experimentally by the introduction of inert immobile masses. When they produce irritation, glycosuria and emaciation may result, as in the human subject. When the tumors interfere with the blood supply so as to initiate degenerative changes in the cells of the anterior lobe, they may give rise to the syndrome dystrophia adiposogenitalis. These facts now experimentally established represent a great step in advance in the elucidation of the obscure functions of a very small yet highly significant portion of tissue.

URIC ACID INFARCTS IN THE NEW-BORN

The ready applicability of modern microchemical methods to the study of various types of nitrogenous compounds other than protein that circulate in the blood has at length made it possible to throw new light on a number of long debated questions regarding metabolism.[1] This now appears to be true in the case of the uric acid infarcts in the form of ammonium urates that are often found in the kidneys of the new-born during the first few days of life. That these infants excrete uric acid in unusual concentration and augmented amounts in the urine has long been known. This relatively and absolutely high output of uric acid has been correlated with associated conditions in the uric acid content of the blood by Sedgwick and Kingsbury[2] at the University of Minnesota. These investigators, as well as Slemons and Bogert[3] at the Yale Medical School, have found that the uric acid content of the blood at the conclusion of labor falls within the limits accepted as normal at other times. The figures obtained from maternal and placental circulation are identical for the uric acid in the blood of the mother and fetus. This indicates that it passes through the placenta by diffusion. In this respect, therefore, Slemons and Bogert remark, uric acid resembles other nitrogenous waste products, ammonia, urea, creatin and creatinin, which are found in equivalent amounts in both circulations. This conclusion also has the support of the findings in pathologic cases. Eclamptic mothers in whose blood the quantity of uric acid is two or three times that of the normal give birth to infants in whose blood the uric acid is correspondingly increased. Soon after birth, however, the condition changes. The content of uric acid in the blood the first three or four days after birth is higher than that of the blood of the same new-born at birth. Subsequently there is a marked decrease in this value at the end of from eight to eleven days from the value obtained (in each case with the same infant) from three to eight days earlier.

Sedgwick and Kingsbury point out that the parallelism between the high uric acid content of the blood of the new-born and the high excretion of this substance during the first three or four days of life is indirect evidence supporting the findings of Wells and Corper[4] and others (in opposition to the results of Schittenhelm and Schmidt[5]) that human fetal tissues possess no uricolytic power; for it would be difficult to imagine so great a production of uric acid if the tissues themselves possessed the power to destroy it. One naturally inquires respecting the genesis of this increment of uric acid. There is no occasion to assume a synthesis de novo, which would be contrary to all current ideas regarding the origin of uric acid. What are its purin antecedents in the new-born?

It is an attractive speculation to associate the increased presence of uric acid with a destruction of leukocytes naturally rich in purin-yielding nucleoproteins. At this period, when uric acid excretion is at its highest, rapid morphologic changes are stated to occur in the blood of the new-born. Sedgwick and Kingsbury speak of the disappearance of the nuclei of many of the red cells, the change in proportion from a predominating number of polymorphonuclear neutrophilic cells to a corresponding predominance of lymphocytes, and the striking decrease in the leukocyte count of the peripheral blood.

The existence of an undue amount of circulating uric acid soon after birth thus seems to be established. The more problematic features of the question are expressed by the Minneapolis investigators as follows: Whether the decomposition of nucleoprotein material, which must be looked on as the cause of this uric acid increase in the blood, is related to the striking changes in the blood cells, particularly in the changes in the partition of the white corpuscles taking place at this time, or to nucleoprotein destruction in other parts of the body, as yet unknown, or to both, must be left to the future to decide. These results fit in well, however, as the connecting link in the theoretical chain of early leukocytosis—fall in leukocytes—flood of uric acid in the blood—high uric acid excretion—uric acid infarcts.

Current Comment

OXALIC ACID IN FOODS

Oxalic acid is widely distributed both in the free state and in combination with bases throughout the plant kingdom. As a result, oxalic acid is introduced into the body as a constituent of vegetable foods. The quantities thus involved are in general exceedingly small and are, so far as is known, physiologically harmless. The acid doubtless occurs in many instances as calcium oxalate in the alimentary tract and escapes absorption. Only in a few plants does the content of oxalic acid reach more significant proportions. Recently attention was called, however, to unexpected fatalities occasioned by eating the leaves of rhubarb in place of spinach. Although the chance for such experiences is doubtless extremely limited on account of the food habits of civilized peoples, it is nevertheless desirable to know something more detailed about the distribution of oxalic acid so that every possibility of harm may be averted. In these days when new foods and unusual sources of nutriment are being urged on housewives by enthusiasts eager to promote the conservation propaganda, one may conceive not only of the chance of employing a product with an unexpectedly high content of oxalic acid, but also of a possible augmented content of the toxic substance by the chance use at the same time of several products containing small amounts. Recent analyses by Arbenz[1] which have become available in this country give the following statistics, in terms of oxalic acid per kilogram of air dry spice or ready-to-eat vegetable, respectively: black tea 14.3, cocoa 4.8, pepper 4.5, rhubarb 3.2, spinach 2.9, sorrel 2.7, dry figs 1.2, roasted coffee 0.8, roasted chicory 0.7, raspberries 0.5, beans 0.45, potatoes 0.4, beets 0.3, currants 0.3, pears 0.2, bilberries 0.2, oranges 0.1, asparagus 0.09, cherries (with seeds), tomatoes and wine grapes 0.08, rutabagas 0.07, cauliflower 0.06, onions 0.05, Brussels sprouts 0.04, endive and melons 0.03, mushrooms, peaches, flour, lemons, celery, plums and apples, a trace; corn meal, rice and chestnuts, none. An added value of these figures lies in the fact that since oxalates in the urine are in part derived from the dietary oxalic acid which is resistant to oxidation in the body, in cases of oxaluria, physicians are accustomed to prohibit those foods which contain most oxalic acid and which are eaten in sufficient abundance to make the total amount thus ingested worth considering. Ordinarily the proscribed dietary articles include tea, coffee, cocoa, spinach, rhubarb, sorrel, pepper, beetroot and beans.[2] It should be borne in mind, however, that not all of the excreted oxalate is necessarily associated with a food source. Some of it may have a microbiotic origin in the alimentary tract; and its possible genesis through imperfect metabolism of certain organic acids is still debated.

THE THYMUS AND RICKETS

It is practically useless to turn to the textbooks for helpful information regarding the functions of the thymus. At best one will find a series of unverified conjectures, debated assumptions, or a frank statement of our ignorance of the real purpose of this organ. The natural association of the thymus with early life has led to the conjecture that the gland plays a part in growth; for it becomes smaller and smaller as the rate of growth declines. The latest though by no means the final evidence indicates that former statements implicating a retardation of growth after removal of the thymus cannot be substantiated by experiment. Halnan and Marshall,[3] for example, found that extirpation of the gland from young animals had no effect on their growth, even when the testes were removed simultaneously. Furthermore, in observations on castrated animals they could find no evidence of any compensatory mechanism between the testes and the thymus. In recent years another possibility of decided practical importance has been given some attention through the assertions of continental investigators.[4] They have reported changes after experimental thymusectomy that correspond somewhat closely to those observed in rickets; and thus the question of the relation of the thymus to bony growth and its pathologic manifestations is again brought into prominence. In an investigation conducted at the Physiology Department of Glasgow University under the new national health insurance medical research scheme, Renton and Robertson[5] have come to a seemingly convincing conclusion in this matter. They have removed the whole thymus successfully in a series of animals which survived long enough to permit adequate observations on their growth in comparison with suitable control animals. Renton and Robertson conclude that thymusectomy of itself does not appear to cause any symptoms. Spontaneous rickets in subjects not operated on gives rise to essentially the same symptoms as the European writers have attributed to removal of the organ; that is, thymusectomy does not make young animals more susceptible to spontaneous rickets, and if they develop it, they do so at the same time and in the same manner as control subjects. The British investigators sum up their findings by the decision that removal of the thymus cannot be held responsible for the onset of rickets or similar bony changes. The alleged pathologic manifestations that have been credited to loss of the thymus have in reality presumably been due to the development of spontaneous rickets in young animals. Thus another promise of discovering a function for this organ has been shattered.

THE RELATIVE VALUE OF FRUIT JUICES

Fruit juices are rapidly finding their way into the daily life of the American people. A few years ago they were limited to the delicacies of the home or to syrups of the soda fountains. Today orange juice and grape juice in particular have found a widespread and growing popularity as agreeable beverages. It is scarcely an exaggeration to say, as does one of the large manufacturing companies in advertising its product, that grape juice has become the national drink. The temperance wave that has swept over this country, taken in conjunction with a vigorous and highly effective advertising campaign on the part of various producers, has helped to secure favor for a refreshing and wholesome beverage. The shortage of sugar at present and the prospect of a necessary restriction in the output of syrups and similar "essentials" of the "soft-drink" industry are likely to increase still further the use of palatable fruit juices. In addition to organic acids which lend a tart flavor to them, these beverages, provided directly by nature, contain a considerable portion of sugars which lend a food value to the product. Thus a glassful of grape juice measuring 7 ounces (210 c.c.) will furnish about 200 calories in the form of sugar; and orange juice is about half as rich in food value. Recently the juice of the loganberry has begun to claim recognition in this category. Analyses[6] made at the Oregon State Agricultural College at Corvallis indicate that this fluid likewise contains from 6 to 8 per cent. of sugar in the acid juice. This lends to it a fuel value of approximately 300 calories to the liter, presumably in the form of available carbohydrates.

HOOKWORM IN THE MINES OF CHINA

The danger of hookworm infection in mines is well known. Hookworm disease is prevalent in many of the mines of California, China, France, Hungary, Sicily, South America and Spain. Germany, it is said, has spent over $2,500,000 in direct outlay to control hookworm infection in a few of its mines. The disease has been brought under reasonable control in the mines of Belgium and Wales. The investigations of the International Health Board of the Rockefeller Foundation have brought to light a rather unexpected source of perennial reinfection of mines that applies to China in a way scarcely realized in the other countries mentioned. As stated recently in THE JOURNAL,[1] the hookworm problem in China presents unique features because of the widespread employment of human excrement as a fertilizer. The disease is thus easily spread into the agricultural districts. It happens that more than a hundred thousand miners, largely recruited from farmers who have worked barefoot in the moist, larva-infected soil, are employed in the mines of Hunan Province alone. The cooperation of the International Health Board has been solicited to provide measures for the control of a difficult situation brought about by this unusual combination of circumstances.

HEAT LOSS AND WATER ECONOMY IN THE BODY

In 1614, Sanctorius wrote, "He only who knows how much and when the body does more or less insensibly perspire will be able to discern when or what is to be added or taken away either for the recovery or preservation of health."[2] Yet the story of this factor of insensible perspiration, the amount of water lost from the body in vaporization, has been most inadequately written. The part played by water in the body is ordinarily overlooked by the clinician except so far as it is expressed in the volume of the urine or in the genesis of an edematous condition. The water which acts as a solvent for the body's waste may thus, perchance, be taken into consideration; but of the water lost from the organism through the respiratory passage and the skin and its rôle in the dissipation of heat from the body, little is known and less is mentioned. The pathway for the loss of heat naturally varies with the temperature of the surrounding air. At a low temperature there is little evaporation of water. Heat is lost in other ways. At an environmental temperature as high as that of the body or exceeding it, there can be no loss of heat by conduction and radiation, so that water evaporation must remove the whole of it. The study of a large number of persons in respiration calorimeters, in this country in particular, has furnished data for estimating some of the factors just referred to.[3] Under an average environmental condition with medium humidity, normal men from 20 to 50 years old excrete on an average 29 gm. (1 ounce) of water an hour — about 700 gm. a day — through the skin and the air passages. In this manner approximately one quarter of the total heat produced is eliminated. Few normal men exhibit variations of more than one-tenth from this figure. According to Soderstrom and Du Bois,[3] the output of water as insensible perspiration is very little affected in disease. When the heat production is increased, the body responds and dissipates the usual percentage of calories in the vaporization of water. When it is necessary to get rid of unusual amounts of heat, the percentage lost in vaporization is increased. Edema seems to have no effect on the water output through the skin; and cardiac and nephritic patients on the whole give figures close to the normal. Just as there is little realization of the extent of the "invisible" water output, so there is too often a failure to appreciate and a tendency to neglect the water content of the intake in the form of seemingly solid food. An illustrative instance has been cited by Soderstrom and Du Bois in the following meal, which might well be given to a nephritic patient: a small dish of farina, a boiled potato, a portion of tomato and lettuce salad, a small dish of junket, and an apple. This ration contains something more than 23 ounces (690 gm.) of water, a quantity sufficient to carry away the heat that leaves in "insensible perspiration" in the ordinary person.

Health of Food Handlers.—During the examination of the food handlers of New York City, made through the cooperation of the health department and the American Museum of Safety, which included the examination of 44,042 individuals examined at the Occupational Clinic and 33,000 by private physicians, Dr. Louis I. Harris and Mr. Dublin of the Metropolitan Life Insurance Company made an intensive examination of 1,748 food handlers considered typical of the entire number. These included waiters, waitresses, cooks, male and female, other kitchen employees and bakers. In the entire group there were ten cases of active tuberculosis, twelve of suspected and three of arrested tuberculosis. Forty-one persons gave evidence of active or suspected syphilis, of which thirty-seven were among waiters. This group furnished forty-six persons with flatfeet and an equal number with varicose veins. Among the 211 waitresses examined, 65.8 per cent. showed anemia; 62 per cent. had varicose veins, and 17.1 per cent. were reported as suffering from some form of menstrual disorder. Four waitresses were found to have syphilis. The predominating defect among cooks was organic heart disease, there being thirty-two who showed cardiac disease. Of the cooks, 161 had marked disturbance of the digestive functions. Among bakers no tuberculosis or active syphilis was found, but there were thirty-eight cases of chronic bronchial conditions; thirty had organic heart disease and thirty-three, anemia. The study is valuable as demonstrating the importance of the examination of food handlers both from the standpoint of protection of the health of the community and for the opportunity it offers for the study of occupational groups. Another point brought out in the course of this study is the lack of uniformity of standards and methods of classification used by the various workers in the field of industrial hygiene.

Medical Mobilization and the War

MEDICAL OFFICERS IN ACTIVE SERVICE

At the present time there are approximately 12,500 medical men in active service. This includes Medical Corps officers (a little less than 550), medical officers of the National Guard Army, and officers of the Medical Reserve Corps. Up to date approximately 17,900 physicians have been recommended for commission in the Medical Reserve Corps.

AMERICAN WOMEN'S WAR HOSPITALS UNIT

The American Women's Hospitals, of which Dr. Rosalie Slaughter Morton is chairman, was organized by the War Service Committee of the Medical Women's National Association of the United States. Women physicians to the number of 1,200 have registered with the committee, for home and foreign service. Already a number of physicians have been sent abroad to work under the authority of the American National Red Cross with which the American Women's Hospitals works in close cooperation.

MEDICAL OFFICERS' TRAINING CAMP AT FORT BENJAMIN HARRISON TO BE DISCONTINUED

The Medical Officers' Training Camp at Fort Benjamin Harrison is being discontinued and the medical officers transferred from the training camp to other stations. Those who have not yet completed their instruction go to Fort Riley and to Camp Greenleaf at Fort Oglethorpe. Orders have been issued from the Surgeon-General's Office, assigning Colonel Ashburn and several of the other instructors to the Surgeon-General's Office and distributing the remaining instructors among the other training camps. The ambulance and field hospital units undergoing training at the training camp are now testing their ability for sustained marching. Ambulance Companies Nos. 15 and 17, with one field hospital unit and headquarters, all of which are motorized, were ordered to start on November 9 on a seven-day hike to Georgia. Company No. 17 and the headquarters unit will go to Camp Greenleaf, while the other unit will go to Camp Oglethorpe. At the same time, two ambulance companies and two field hospitals, the sixth and fourteenth in each case, provided with mule motive power, received similar instructions.

SALVAGING CLOTHES FROM BATTLE-FIELDS AND CAMPS

The English War Office has set up at Dewsbury a department for the purpose of repairing, restoring and utilizing old uniforms and fabrics recovered from the army and navy. All discarded clothing and fabrics of every sort from the battlefields and camps and from the navy are collected, put into bags and shipped to Dewsbury, where the material is sorted into that which can be cleaned, repaired and made usable, and that which must be discarded as rags and put through processes by which it can be made useful as new material. As many as ninety truckloads of this material have been received at this station in a single day. About 350 women are employed as sorters, who pick out the garments that are in condition to be repaired and used again. All articles capable of being restored are sent to a local firm of dyers and cleaners, by whom they are cleaned. Then they are repaired and reissued to the troops or for the use of German prisoners of war. With a high standard of efficiency and a large turnover, the cost for each article, including large repairs, amounts to about 28 cents. In this way, it is said in the report regarding this matter from U. S. Vice Consul Hamilton C. Claiborne, Bradford (*Commerce Reports*, November 5) that $300,000 worth of uniforms have been salved up to the present. In ten months, a total value of material received and disposed of at Dewsbury was over $3,000,000, and the net profit shown on such material at all the stations amounts to a very large sum. Details are given in the report of the amount of material received, the various channels in which it is disposed of, and the uses to which it is put.

CALIFORNIA'S VENEREAL DISEASE PROGRAM

Last summer there was held in San Francisco a conference on prevention of venereal diseases in California, in the interest of soldiers, sailors, and civilians. The program then outlined has been embodied in regulations recently by the state board of health.

The regulations for the prevention of syphilis and gonorrhea require those in attendance on a case of either of these diseases, or a suspected case, to report the case immediately to the local health officer, who in turn will report it to the state board of health. Such reports are to be made by patient's office number or initial only, but the number or initial used must refer definitely to the physician's record of the case. Physicians are expected to furnish, when reporting such cases, any available data that may be useful regarding the sources of infection and must teach the patient how to prevent the spread of the disease, its seriousness, the necessity for prolonged treatment, and must furnish the patient with approved literature on the subject.

Every city, county, and other health officer is directed to use every available means to ascertain the existence of syphilis and gonorrhea within his jurisdiction. He is required to investigate immediately all reported or suspected cases of syphilis in the infective stage, and of gonorrhea, and may inspect, examine, isolate, and disinfect persons, places and things. He is directed to make examinations of persons reasonably suspected of having syphilis in the infective stage or gonorrhea All prostitutes are to be regarded as coming within the suspected class, but the health officer is forbidden from issuing to such women certificates of freedom from venereal disease. The health officer may require the submission of specimens from cases or suspected cases of syphilis or gonorrhea, for the purpose of examination at a state or municipal laboratory, and it is the duty of the attending physician to furnish such specimens when called on to do so.

Local health officers are directed to isolate reasonably suspected persons whenever isolation is necessary to protect the public health. In establishing isolation the health officer must define the limits of the area within which the isolated person and his immediate attendant shall remain. Isolation is not to be terminated until the patient has become noninfective, unless permission is given by the state board of health or the secretary of that board. Cases of gonococcus infection are to be regarded as infective until at least two successive smears taken not less than forty-eight hours apart fail to show gonococci. Cases of syphilis are to be regarded as infective until all lesions of the skin and mucous membrane are completely healed.

Health officers are directed to use every proper means of repressing prostitution, and are to report to the Bureau of Venereal Diseases any unusual prevalence of syphilis or gonorrhea and any unusual local conditions tending to favor the spread of these diseases.

CLINICS AND HOSPITALS

In preparing a list of approved venereal disease clinics and hospitals, the state board of health is aiming to raise the standards of some of the existing dispensaries and hospitals, to encourage the formation of additional public dispensaries where needed, and to assist persons needing institutional treatment to ascertain which institutions have adequate staffs, equipment and standards. Minimum standards are prescribed for dispensaries and for hospitals.

A dispensary, to be approved for the treatment of syphilis, must treat patients suffering from that disease in a separate department or in the department of dermatology, but there is no analogous restriction with respect to dispensaries for the treatment of gonorrhea. In either case, however, the dispensary must be open at least three times a week, day or evening, and the staff must be adequate both in number and in training. Rooms must be well arranged, and every dispensary must have at its disposal beds for isolation and treatment. Laboratory facilities and equipment, with instruments and apparatus, must be provided. In cases of syphilis, microscopic examinations of the suspected initial lesions must be made; Wassermann tests must be performed in the dispensary laboratory or other approved laboratory, and suitable tests and observations shall be made of all patients for a period of not less than two years after the conclusion of adequate treatment. Salvarsan or an accepted equivalent must be administered to all patients suffering from syphilis, unless there are contraindications.

In an approved dispensary for gonorrhea, systematic examination must be made of the discharges, and facilities for urethroscopic and cystoscopic examinations must be provided and be regularly employed by the attending clinicians. Patients must not be discharged as cured until after repeated negative clinical and microscopic examinations. Adequate facilities must be provided for asepsis and antisepsis.

In dispensaries of both kinds adequate records must be kept and an annual report must be made. The clinicians in attendance must themselves devote the amount of time necessary for intelligently informing new patients of the seriousness of their diseases, the necessity for treatment until cured, and the precautions to be taken to prevent the spread of the infection to others, and in addition the dispensary must furnish approved literature on the subjects. A dispensary will not be approved unless a social service department is maintained and adequate measures adopted to procure the regular attendance of patients. If it becomes necessary for any reason to discharge a patient still uncured, the patient must be referred to an approved clinic or to a reputable physician

In general the standards for hospitals for syphilis and gonorrhea are similar to those for dispensaries, but it is specifically provided that patients having venereal diseases must be accepted under the same conditions as other patients.

NEWS OF THE TRAINING CAMPS

At Fort Oglethorpe

Lieutenant McDonald of the Signal Corps has been detailed by the War Department to make a series of moving pictures of the work being done at Camp Greenleaf toward training civilian doctors for military work. If there are any physicians left in this country who imagine that all they have to do in order to serve in the Medical Corps is to change their civilian clothes for a uniform and begin "pushing pills" to the sick soldier, please advise them to see these pictures if they are ever exhibited in their communities. Let them see the workings of an ambulance company, field hospital, regimental or sanitary unit, and then wonder whether they could take charge and run one as smoothly as the trained man. Surprising as it may be to them, doctors are in charge of these outfits, have to run them, and are responsible for all properties connected with them, as well as the training of the enlisted personnel. Moreover, these doctors were untrained civilian surgeons or physicians four months ago.

Majors Van Wart and Owensby have been making a mental survey of the camp for the past three weeks.

Major L. Owen has been relieved from duty at Camp Greenleaf and assigned to the Surgeon-General's Office. The camp has suffered a distinct loss, for Major Owen was one of our most popular and efficient instructors.

Lieutenant-Colonel Talbott, M. C., has been assigned to Greenleaf as camp inspector. Colonel Talbott has had many years' experience in this line of work, and from the amount of interest he has inspired in the student body, we feel safe in predicting "more laurels for his crown."

Major William Pepper, M. R. C., formerly dean of the Medical Department of the University of Pennsylvania, has been made adjutant.

Major Alexander Abbott, M. R. C., has been placed in charge of the school of hygiene recently established at the camp.

Major Walter Weisser has been assigned as provisional director of field hospitals.

Major Bell, formerly connected with the Royal Army Corps, has given a series of lectures on his work in France. Major Bell's ability as a speaker and his unusual opportunities for observing the medical work done in France made his lectures the most interesting in the course.

The Camp Greenleaf Military Society was organized last Friday night. Col. Henry Page, M. C., the commandant, was elected honorary president, and Major Alexander Abbott, president. The aims, objects, etc., of this society are worthy of a more lengthy notice than can be given in this letter—so more about it another time.

Everything is being made ready for taking over the work of the M. O. T. C. at Forts Riley and Benjamin Harrison. The buildings of the R. O. T. C. will be turned over on November 27, which will give accommodations for an additional 5,000 men.

Lieutenant-Colonel Carswell has been relieved from duty with the field hospitals and ordered to San Antonio, Texas. Before leaving, Colonel Carswell was presented with a beautiful wrist-watch by the officers in his command, as a token of their appreciation of his untiring efforts in making the field hospitals one of the best outfits in the country.

Major M. Ashford, M. C., is convalescent from an attack of the grip, and has resumed command of the ambulance companies.

At Fort Benjamin Harrison

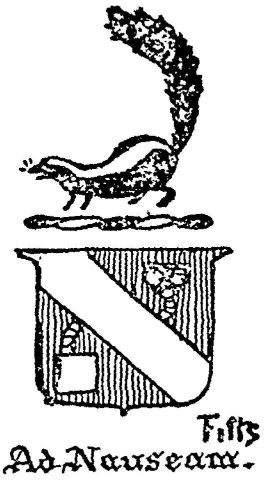
CLOSING OF THE CAMP

What is left of the members of the medical officers' training camp at this post will continue their training at Fort Oglethorpe, Ga., as the date for closing the camp here is at hand. The thousands of medical officers who have gone through the training at Fort Benjamin Harrison since the first of June are scattered far and wide. Most of them are still in this country, assigned to base hospitals, field hospitals and regiments. Not a few are in France or at embarkation points.

It is gratifying to the pride of the medical profession for the War Department to admit that the medical branch of the service is prepared to the highest point of efficiency of all. True, it was not necessary to teach us the most obvious part of our work—that of medicine and surgery—as none could receive commissions without first undergoing examination or furnishing evidence of a thorough medical education. However, it has been necessary to begin at the bottom in the education along military lines. Very few had any knowledge whatever of the military side of the life which it bids fair to believe will be theirs for three or four years. This they had to learn, and it has been accomplished in a remarkably short space of time.

GAS DEFENSE

The last of the military lessons, and perhaps one of the most interesting that has been introduced, is that latest flower of Kultur, the gas squad, the Legion of Frightfulness, its insignia a skunk with tail rampant, bar sinister, and the motto "Ad Nauseam."



Insignia of the Legion of Frightfulness.

Three instructors, a trio of frightfulness, descended as a gas cyclone from Fort Sill, Okla. With them arrived an assignment of the gas masks adopted by the United States Army for protection against the poisonous and other gases being used in the present war.

Poison gas was first used in modern warfare, April 22, 1915, by the Germans against a sector of fresh Canadian and French forces, with the double purpose of destroying the morale of the fresh contingents and causing casualties. This was followed by a fresh trial, defensive, against the French attack on the 26th, which was likewise successful. Its use soon became general. This was cloud gas, and as its efficacy depended definitely on atmospheric conditions, gas shells soon were substituted, and now constitute 30 per cent. of the shells used.

The objects in the use of gas are: (1) putting men out of action (casualties); (2) hampering men in artillery, delaying maneuvers; (3) preventing supports and supplies from being brought up, and (4) inspiring general terror.

The gas is used in the form of cloud gas and gas shells in the following varieties:

1. Lacrimatory—direct primary effect on the eyes.
2. Asphyxiating—direct corrosive and irritating action on the respiratory tree.
3. Paralysant—causing central nerve paralysis.
4. Miscellaneous—nauseating and blistering compounds.
5. Accidental—nitrous fumes and carbon monoxid from explosion of mines and high explosives.
6. Mixed.

To combat gas attacks, gas masks and warning are employed. The masks are box respirators of a regulation type. They consist of a canister containing layers of cotton, filters, charcoal, a neutralizing agent—soda lime—and an expiratory shutter valve. Masks are provided with mouthpieces, nose-clip and goggles, fastened into rubber tissue, to protect against tear gases. Warnings come from various sources—aeroplanes and outposts, the whistling sound of the gas itself, which can be heard for 200 yards, smell, the appearance of a cloud of any color, and the loss of the taste of tobacco.

As there is short time allowed to don the mask when in action, drills to speed up its adjustment must be given.

GAS DRILL

There are three preliminary commands: 1. "Mask at carry." Here the satchel is swung over the left hip, with the sling passing over the right shoulder. 2. "Gas alert." The satchel is advanced to the front of the body, with both arms through the sling, and flap open. 3. "Gas" by numbers (adjustment of mask): 1. The right hand is thrust into the satchel and the mask seized firmly, the tube fitting into the palm of the hand, with the fingers grasping the eye-piece. 2. The mask is brought smartly from the satchel, with the fingers grasping the edge of the face-piece, and is brought close to the chin, which is thrust forward. 3. The mask is brought upward, the chin dug into it, and at the same time the elastic bands are placed over the back of the head. 4. The metal breathing tube is seized in the right hand, and the rubber mouth-piece is placed in the mouth. 5. The nose-clip is attached well down over the nostrils. (This is necessary to prevent nose-breathing, as all of the air taken into the lungs must come through the canister containing the antidotes.)

This drill is continued to a point of efficiency whereby it is possible to adjust the masks from "Masks at carry" to the finishing touch of fastening on the nose-clip, in six seconds.

For the purpose of this drill the innocent Docs are ruthlessly lined up, preparedly gassed by lectures, and then forced to don their masks. One look, and there is a mad rush for cameras, to perpetuate their first appearance in the gas masks. That night 300 letters go home, telling of the marvelous experiences and hair-breadth escapes from the gas clouds—shell gas and lecture gas.

As a lesson in anatomy, the gas drill is excellent, and many learn for the first time, while adjusting the nose-clip, the exact position of their noses. The masks also demonstrate that drooling is not exclusively an attribute of infancy, and that bibs may be used to advantage even by medical officers. The constant irritation to the mouth of the tight-fitting mouth-piece fastened to the end of the breathing tube causes an excessive flow of saliva, which escapes through a drip tube out on the chest. It is not an uncommon experience at the beginning of this work, and until one is accustomed to the mouth-piece, for the flow of saliva to be so great as to soak through the clothing.

The first sensation of uneasiness over, and the novelty past, all found to their surprise that the mask, although grotesque in appearance and somewhat clumsy, could be worn without discomfort, and that it permitted perfect freedom in breathing.

This course of instruction, patterned after the British organization, occupies a week, divided between lectures, drills and demonstrations with actual gases at the gas house. It is intended to cover the subject thoroughly and to show the method of protection against poison gases, describe and demonstrate the kind of gases used, and, in the Medical Corps, to give information regarding the symptoms and treatment of those unfortunate victims of this terrible phase of modern warfare.

News Notes from Fort Riley

Preparations for winter are now in progress. Barracks are being banked with earth or supplied with frame or stone underpinning. Stoves have been installed in all barracks and mess halls. Following the blizzards and cold snap of last week, we have had nearly a week of ideal Indian summer weather. Warm, mild sunshiny days and cool, pleasant nights make ideal weather for field maneuvers and bivouacs.

The remnants of Companies 5, 6, 7, 8 and 9 have been consolidated into one company and transferred to No. 6 barracks. This combination is known locally as the "scrambled eggs company," although its own members prefer the title of "Rainbow Company."

No. 7 Mess Hall has been converted into an officers' reading room and library. It is furnished with stoves, tables and chairs, and forms an ideal place for study, reading and letter writing. Medical journals, popular magazines and books are plentifully supplied. This room is generally patronized, and fills a long felt want in the camp.

On Thursday and Friday of last week, companies were taken in a practice march and bivouac to Hay Camp Springs, each man carrying his full equipment with the exception of his bedding roll. The boys supplemented the regulation field reserve ration with rabbit stew, thus furnishing a practical illustration of living on the country.

Field tactics in the morning and regimental maneuvers in the afternoon have given Companies 8 and 9 abundant practice in equitation, on some days giving an opportunity for six or seven hours a day on horseback. Each student officer, in turn, acts as a regimental surgeon, brigade and division surgeon, and is required to issue his orders and carry out his plans. Instruction and practice in locating regimental aid stations, ambulance dressing stations and field hospitals have been greatly enjoyed, the terrain of the Fort Riley reservation affording unusual opportunities for such work.

Major K. W. Kinnard, M. C., U. S. Army, has been ordered to the medical officers' training camp from Camp Sherman, Chillicothe, Ohio, to act as director of field hospitals.

Major George G. Davis, M. R. C., of Chicago, has been relieved as director of field hospitals and assigned to the command of Evacuation Hospital No. 1.

BIVOUAC PRACTICE

One of the things much looked forward to by those men who really enjoy outdoors is the practice march and bivouac. The company, each man equipped with his shelter half, rope and pins, haversack and canteen and carrying the standard reserve ration, is marched out to Hay Camp Springs, which is a delightful place for a bivouac. The pup tents are pitched on each side of the company street, and then the tents, as well as the officers' personal belongings, are carefully inspected by the officer in charge of the party. To accustom the officers to the use of the Lyster bag, no water is permitted to be used until it has been properly chlorinated in the bags, although the water at the springs is of the best. The reserve ration alone is permitted, and no extra food or delicacy of any kind may be taken. Each officer cooks for himself; and the bacon, crisply fried in the meat can, never tastes better than when on such an expedition. The bread comes in two packages, and is in the form of a cracker. Without butter these crackers would be unpalatable indeed; but after being dipped into hot water (heated in the cup going with the canteen) and then mixed thoroughly with the melted bacon fat, they form quite a savory dish. Coffee is made, and completes the menu. While bacon, hardtack and coffee with sugar but without milk may sound to the uninitiated an insufficient meal, it is far from being such. The caloric value is amply sufficient for a heavy man doing heavy work.

To make oneself comfortable in a pup tent requires, first, that one be thoroughly tired, and second, that one be not too badly coddled by the refinements of civilization. The average officer sleeps well, albeit, if the night is cold, it may be an effort to keep warm. Blessed is he whose tentmate does not snore; for with two men in a space as small as that encompassed by a shelter tent, the relation of one to the other is much like that of a pair of spoons in a case. For breakfast, more reserve ration, for luncheon ditto. Cleaning the dishes is not an extensive process, but one that would put the average housewife to her wit's end. Yet with some time and much rubbing, it can be done and done satisfactorily too.

The allowance of equipment taken on the wagons is 50 pounds, which includes absolutely everything. To make sure no one "hunches," the rolls are weighed.

Company 8 in its bivouac had a rabbit hunt. Forming a circle, they managed to scare up and kill some score or so of rabbits, which were promptly transformed into savory stew. The next day's march home finds each officer with a new idea as to just what a bivouac means and how it feels to be on the reserve ration.

NEWS OF THE CANTONMENTS

Twenty-Eighth Division, Camp Hancock, Augusta, Ga.

Representatives from the Surgeon-General's Office recently visited the camp to inquire into the shortage of equipment.

Major Dillinger recently returned from a short leave of absence. He is assistant division surgeon. He has been active in Pittsburgh politics, and was recently a candidate for councilman.

A course of intensive training for the medical officers was begun here, November 1. Among the lecturers are Lieutenant-Colonels Keller and Crookston, Majors Frescoln, Heffelbower, Crampton, Schaeffer, Dillinger, Swayne, Hogan and Schwartz, Captain Stone and Lieutenants Wood, Smith, Laws, Snyder, Seeley, Hollister and others. The course will include the modern advances in military surgery, trench sanitation, French and antigas warfare.

Thirty-First Division, Camp Wheeler, Macon, Ga.

BASE HOSPITAL NOTES

There are at present under treatment in the hospital 1,322 patients, although three wards are still incomplete. Three fourths of the patients have measles, and unless there is an abatement of the epidemic, it will be necessary to occupy the hospital tents pitched for use in case of need. Six tents, each with a capacity of twenty-five patients, are in place, and will be used for convalescent measles patients only should the emergency arise. Heretofore it has been possible to care for all patients under roofs, though all porches and the machine shop have been utilized to that end.

Notwithstanding the crowded condition of the wards, the patients are content, and there are few complaints. When these are made they are at once investigated thoroughly, and relief given as indicated.

The mortality rate speaks for itself, and shows conclusively that even under great difficulties sick and wounded men can be handled satisfactorily. As sequelae there have been nineteen cases of pneumonia, with two deaths.

It should be gratifying to the profession to know that practically every one, from the commanding officer to the lowest private, has risen to the occasion of this emergency; but it is no more than is to be expected. Conditions arise in war which must be overcome, and they are overcome.

The enlisted personnel has been increased by eighty men arriving from Camp Lee. It is believed that there are now enough.

The nurses' quarters are nearing completion, and will be ready for occupancy in a few days, as will the isolation and neuropsychiatric wards. It will probably be necessary to use the latter two for measles patients for the time being.

The mess officer and kitchen personnel are accomplishing the almost impossible task of feeding 1,700 people with a mess hall and equipment intended for 500.

PERSONAL

Captain Pratt has begun his course of instruction in gas defense, which is extremely interesting.

Major Harrold, M. C., acted as one of the judges in the athletic competition at the Georgia state fair.

The Georgia branch of the Daughters of the American Revolution intends to present an ambulance to the Thirty-First Division, for service in France.

Major Pearce Bailey, chief of the neurologic division of the medical service, visited that division last week.

Captain Mitchel, Sanitary Corps, is now on duty with the division as sanitary engineer.

ONE HUNDRED AND SIXTH SANITARY TRAIN

Recently a short problem was workeed out west of the Marion road, 2 miles north of the base hospital site. The tag-patients were detailed from the Florida and Alabama field hospital companies. Work of the regimental detachment was carried out by the hospital corps detachment of the One Hundred and Twenty-Second Infantry, commanded by Major Lindrome. The dressing station was established and the wounded evacuated to the ambulance company dressing station from the regimental collecting point by Ambulance Company No. 121, Capt. Robert F. Ashworth commanding. From the dressing station the wounded were evacuated by the motor ambulances to a theoretical field hospital established at Section 19. Considerable improvement was noted in development of coordinated effort over the problem of last week.

The ambulances of Ambulance Company 124 (mule-drawn) are in process of receiving their initial coat of olive-drab paint, showing in striking contrast to the familiar dark painted bodies.

Additional details of thirty-five men were made for special duty at the base hospital the past week in order to meet the increased demands of the heavy work incumbent on the base hospital. Though further depleting the enlisted personnel available for routine drill and instruction purpose within the train, it is evident that the training received in the actual care of the sick will be of great value in the future work of the train.

Major Cornelius F. Holton, commanding Field Hospital 123 (Georgia), by direction of the division surgeon has pitched the complete ward-tent equipment on the base hospital grounds for use should the emergency require.

Lieut. Daniel P. Campbell has returned from his short leave of absence a happy benedict. Mrs. Campbell has taken up her residence in Macon.

It is with deep regret that we note our first casualty in the train in the death of Private Aubrey Moore of Ambulance Company No. 123, a young man of sterling quality, with great promise of soldierly development. In attending the sick in one of our detailed detachments at the base hospital, he contracted lobar pneumonia. Even as on the field of battle, "he died in line of duty."

The sick rate of the sanitary train reflects credit on the officers and men of the train, being the lowest of any organization in the division.

Again the hopes of the train commander, Major Keenan of Massachusetts, have been raised in the anticipation of the carrying out of the promise of a dinner of "possum and 'taters." As reported two weeks ago, the prospective dinner was stolen from his cage. However, Friday morning a fine fat subject of the possum tribe arrived from some unknown source, and at the present writing we are sure, at least, that said possum is deceased and ready for the oven. Massachusetts still has hope of being convinced that this famous dinner combination is what is claimed for it.

The weekly social of the officers and ladies of the train, with their guests, was held as usual in the recreation hall. The Florida field hospital orchestra furnished the music for dancing. The usual buffet luncheon was served.

The completion of the framing of the tents for cool weather has insured more comfortable quarters. The acquisition of considerable more clothing now renders comparative comfort, especially at night.

Major Job C. Patterson, director of field hospitals, visited last Sunday at the neighboring settlement of Columbus. We have no definite information, but we suspect that a young man's thoughts may turn "lightly to love" even though spring is several months away.

Thirty-Fourth Division, Camp Cody, Deming, N. M.

Enlisted men of the division already present number about 23,000. During the past two weeks the number has been rapidly increasing. The camp is a collection of human beings of wonderfully good quality, and life in it induces a daily growing respect for the man power of America. These men, from our middle western plains, are a bulwark of defense on which the nation may confidently rely.

The spirit of the camp is excellent. It is well expressed in an address delivered by Brigadier-General Mauldin in command of the division on the occasion of the opening of the School for Medical Officers. He said:

> We face an enemy capable and determined, and the task before us will require the best that each man in our Army has in him. But the Army has already accomplished things that seemed impossible. In this war the Medical Department faces the greatest demand that has ever yet been made on the medical profession. The response has been good. Men have made great sacrifices in order to serve the nation, and these sacrifices are appreciated. Our medical officers are ready to work all the time with all their capacity. More than that is required. We must work together. Cooperation with each other and with the rest of the Army is essential if we are to meet the new and unconsidered duties by which we shall be confronted in the war, and win. But we know that each man will give his utmost effort to the United States, and that he will coordinate his efforts with those made by his fellows. We know that each man will be filled with the determination to win, and we shall win.

During the week ending October 22, 2,555 men were examined by each of the medical boards. Of these there were rejected on account of disease by the tuberculosis board (2,342 examined), 10; by the cardiovascular board, 9; by the ophthalmologists, 12; by the board examining the mentally defective, 5. The results of the work of the tuberculosis board are of interest in that they indicate the probable percentage of incidence of pulmonary tuberculosis among the supposedly healthy members of the communities in our north middle states. Cases discovered by this board are incipient. The advanced ones have already been thrown out by the physicians who examined the men on enlistment. This percentage has been 0.5 per cent., and it is probable that during the autumn months this percentage of individuals in any of these communities is developing active pulmonary tuberculosis. Special effort is made to detect these early cases. Organization commanders are requested to send for examination all men in their command who have cough and expectoration, or who show lassitude and inability to perform full duty. New cases are promptly discovered, and the probability of recovery of those thus early detected is great.

VENEREAL DISEASE

The number of cases of venereal disease contracted in or about the camp is gratifyingly small. Since the division came to Camp Cody, Aug. 25, 1917, only eleven new cases of gonorrhea and one case of chancroid have developed. When it is considered that the total number of men in the camp is over 22,000, this affords a gratifying evidence of the efficiency of the measures of prevention that have been instituted. This is a percentage of 0.0036 per month. Many of these patients had not taken the required prophylaxis. They thus come under the operation of G. O. 31, 1912. They are deprived of pay while off duty, and they will be tried by court martial for neglect of duty and failure to obey orders. In contrast with this small percentage of cases contracted here, it is very interesting to note that 440 cases were imported. The anxiety that has been expressed concerning the dangerous moral environment of our troops in camps would be better directed toward the home environment, since the number of cases contracted at home is to the number of cases contracted at camp as 38:1.

The treatment of these cases is a matter of great importance in the Army, since there depends on it the effectiveness of many U. S. soldiers. That which is required in this camp is stated in the following memorandum:

MEMORANDUM ALL SURGEONS, THIRTY-FOURTH DIVISION

The division surgeon desires that the following recommendations be followed as closely as equipment will permit in the treatment of venereal diseases at regimental infirmaries:

GONORRHEA

1. Patients must be instructed in personal cleanliness. They will be advised to wash their hands after each urination and will be cautioned against the danger of infection being carried to the eyes by unclean hands.

2. It is necessary in the thorough treatment of gonorrhea that the penis be cleansed before each injection, with a nonirritating soap and water. Frequently the foreskin is not retracted and the penis is not thoroughly cleansed. The practice of sealing the urethra by means of a small pledget of cotton, which is held in place by retracting the foreskin over the head of the penis, should be avoided. This tends to prevent drainage, and reinfection frequently takes place. The best method of protecting the clothing is to put a piece of clean cotton over the end of the penis to extend about one-third way back and which can be held in place by means of a rubber band.

3. After the above cleansing process, the patient will be advised to urinate before each injection. As gonorrhea is an acute infection of the mucosa of the urethra only, it is necessary that whatever treatment is carried out be nonirritating and one that will not increase the inflammation. When too strong injections are given, posterior urethritis is frequent, and injury to the mucosa occurs which results in chronic gonorrhea or gleet. It is advisable to begin with an injection that is not stronger than one fourth of 1 per cent. protargol. This can be increased, depending on the patients' tolerance and the amount of discharge. Injections should be given every two to six hours by the surgeon, or under his supervision. Care should be taken that the syringe does not traumatize the mucosa and thus open up new avenues of infection. The urethra should not be overdistended, but should be comfortably filled so that the patient has no difficulty in holding the drug at least ten minutes.

The surgeon must insist that all patients drink a large quantity of water, which can be made bland by the use of small doses of sodium bicarbonate. Hexamethylenamin and other urinary antiseptics are very useful, but must not be used in large enough doses to produce irritation of the sphincter and posterior urethra. The injection of large quantities of water causes the urethra to be continually flushed from within out, which is the desired effect. Erections at night should be avoided. Advise your patients to sleep with a little less than the usual amount of covering. It is not desirable that they be chilly or cold, but too much warmth frequently induces erections. When necessary, bromids or other nerve sedatives should be used to control erections.

4. Glass syringes are frequently broken when boiled. They can be disinfected and the gonococcus killed by immersion in a phenol (carbolic acid) solution. Care should be taken that they are thoroughly washed before being used.

5. Much better results can be obtained when using silver salts if the surgeon will have the solution freshly prepared.

6. Frequent examination of the urethral discharge is necessary. This can be accomplished by referring the patient to the base hospital with a note asking that a smear be made. The proper time to obtain such a specimen is before the morning urination.

7. Gleet or chronic gonorrhea is the result of infection into the submucosa of the urethra. It is necessary in this group of cases, after the gonococcus has disappeared, to sound the patient regularly. This will be done by the chief of the genito-urinary clinic at the base hospital, and such patients can be directed to see this officer at the Friday conference and at such other times as the officer may direct.

8. Chronic cases that do not respond to the usual treatment as carried out at the infirmary should be referred to the officer in charge of the genito-urinary clinic, base hospital, for diagnosis and suggestions relative to treatment.

9. Patients requiring endoscopic or cystoscopic examinations will be referred to the base hospital.

CHANCROID

1. All suspicious sores will be referred to the base hospital for diagnosis before treatment is begun. Dressings and medicines of all kinds should not be used before the officer in charge of the laboratory has had an opportunity to obtain some serum for dark field examination. Chancroid is best treated by soaking the penis in some mild antiseptic solution which should be comfortably hot. A saturated solution of argyrol, or the pure crystals of argyrol, applied to such a lesion will usually bring about quick recovery. The inguinal adenitis can usually be controlled by applications of blue ointment. Vaccines are of some use in very chronic cases. The surgeon must be on the lookout for a double infection, as frequently a lesion begins as a chancroid, and later a syphilitic infection develops. When suppuration of the inguinal glands occurs, patients should be immediately referred to the base hospital for treatment.

CHANCRE

1. As mentioned above, every suspicious sore should be examined by the officer in charge of the laboratory, base hospital, so that if syphilis is present, treatment can be started at once. It is necessary to have sterile distilled water for intravenous treatment. Patients requiring salvarsan or neosalvarsan or the intramuscular injection of mercury will be referred to the base hospital. These patients need not remain in the hospital, and can be returned to duty the same day. The Wassermann test is not positive in early syphilis, so that it should not be depended on for a diagnosis. The test should be used in every suspicious case except the early primary lesion. In these cases, as mentioned above, the serum examination for spirochetes is positive in every case of syphilis. A negative Wassermann test does not mean that syphilis is absent. It is necessary that the surgeon study the case together with the laboratory findings before making his diagnosis. Provocative medication is frequently necessary. Mercury can best be used by the inunction method. When this method is used, it is necessary that the surgeon personally supervise the rubbing so that he knows at all times the amount of mercury the patient is absorbing. A good plan to follow is that the men be required to sleep in their undershirts and that the mercury be rubbed into the torso. They should bathe but once a week, at which time the undershirts can be changed. Five treatments per week are sufficient. A course of treatment should take six hours, and consist of thirty rubs.

2. Cases that should be referred to the base hospital: acute epididymitis; posterior urethritis; prostatitis; seminal vesiculitis; suppurating buboes that require drainage; cases for intravenous medication; cases for Wassermann test; in addition, the above mentioned cases for diagnosis and special treatment.

A copy of this memorandum will be posted in a conspicuous place in the room in which venereal treatment is given.

By order of Lieutenant-Colonel.

Some other lines of sanitary work in progress are important. Food is being carefully inspected. All that comes into camp must conform to certain standards. Meat passes the local inspector of the BAI before delivery to the quartermaster, and between the quartermaster and the companies it must pass that of the camp inspector. Milk must measure up to the standards set by the BAI. It must not score less than 75 per cent., and dairies are inspected once in thirty days. Bacteriologic examinations of milk are made, and those dairies whose produce fails to be approved are denied permission to sell to the camp, nor are ice cream factories, bakeries, etc., using this milk permitted to sell to the camp. Canned goods are inspected before issued. Those cans that are leaky and those showing the presence of gas are rejected. The laboratory at the base hospital is now equipped to conduct these examinations for the camp.

The examination of all those concerned in the preparation or handling of food to discover carriers of typhoid or paratyphoid has resulted in the detection of one paratyphoid carrier, who was promptly relieved from duty in the kitchen.

Incoming troops are examined on the train for contagious disease. At the end of their long trips, those trains pull into our sidings, and our newcomers are given a welcome by the band; but before they come within hearing of the martial music, Major Kenney, M. C. N. G., and his staff are already inspecting them, and some unfortunates go from the train directly to the contagious wards of the base hospital. All the others must go to the detention camp of the depot brigade, where during two weeks they carry on in isolation the work of training, before they are admitted into full membership and good standing in our healthy community. Everywhere throughout the camp cases of contagious disease that appear are promptly removed to the hospital, and the contacts, that is, those living in the same tent or in immediate association with them, go to the contact camp out in the unmitigated desert, there to enjoy a noninterrupted view of the far away mountains during whatever leisure is permitted them by the system of intensive training which makes its presence felt even there. The contact camp was commanded by a line officer, there being about 300 men in it; but as this arrangement proved unsatisfactory it is now in charge of Ambulance Company No. 134, commanded by Lieut. F. H. Roost. The Medical Department has taken it over entirely.

Thirty-Fifth Division, Camp Doniphan, Fort Sill, Okla.

A quadrilateral, the monotony of its low and once whitewashed stone walls broken only by the regularly spaced chinks through which one time blazed the fire of the trooper's rifle—such is old Fort Sill.

WORK OF THE DIVISION SURGEON

The sanitary and medical care of the camp is in charge of Lieut.-Col. W. T. Davidson of the Regular Army, under whose efficient and experienced leadership the camp has fared exceptionally well so far. He is ably assisted in this work by Major Carl Philipps, M. R. C., sanitary inspector, and Capt. W. L. Gist, M. R. C., adjutant. One of the difficult problems that the division surgeon had to solve was represented in the water supply. Owing to an unprecedented inadequate rainfall, which has continued now for a period of almost eighteen months, the impounded waters of Medicine Lake, which supply the camp, had become exceedingly offensive from an overgrowth of algae. This condition has now been quite satisfactorily overcome by adequate methods of treatment, to which the present cold weather has given considerable assistance.

The immunization of the troops against typhoid, paratyphoid and smallpox has practically been completed. In addition to these preventive measures, all cooks and those who handle or prepare food are being subjected to special examination to determine their freedom from typhoid germs. So far no carriers have been found.

A special course of instruction in matters pertaining to camp hygiene and sanitation, as well as the special features in the examination of recruits, has been arranged for and is well attended and appreciated. Special examining boards for tuberculosis, cardiovascular, and nervous and mental diseases are also active in weeding out the unfit.

The venereal disease problem also, here as elsewhere, forms one of the important considerations. Since October 1 there have been 322 venereal disease patients under treatment in this division; this makes approximately 1.3 per cent., a figure not excessive when compared with civil life statistics, especially when one considers that under the draft many men already infected are brought into camp.

The general disease incidence for the camp has been low thus far, reaching not quite 2 per cent. Contagious diseases have been relatively infrequent. Since the establishing of the camp in August there have been all told but two cases of cerebrospinal meningitis, nine of diphtheria and fourteen of pneumonia in the division. A case of anthrax with recovery may be mentioned among the more unusual infections that have come under observation. An outbreak of measles in one of the companies was promptly controlled by rigid isolation, and no new cases have been noted.

It is the opinion generally here among medical men that the absence of alcohol has added greatly to the efficiency of the men and to a lessened morbidity.

BASE HOSPITAL NOTES

Pending completion of the base hospital, the sick are being taken care of at the post hospital of Fort Sill. The opening of a number of wards of the new base hospital has made the care of the patients less difficult, however. When all of the buildings are completed there will be hospital accommodations for more than 1,200 patients, a little more than 3 per cent. of the total command. Past experience of the Army Medical Department has shown that this is about the average of sick in large commands.

Major P. B. Connolly of the Regular Army is in command at the base hospital, and the chief branches of the service under him are in the hands of the following Medical Reserve Corps officers: Major A. W. Barksdale, surgery; Major S. Strauss, medicine; Major A. C. Magruder, eye, ear, nose and throat, and Major G. C. Ruhland, laboratories.

Eighty-Third Division, Camp Sherman, Chillicothe, Ohio

Camp Sherman is situated on a broad plain of alluvial deposit on the west bank of the Scioto River. It is 2 miles north-northwest of Chillicothe, which is 50 miles south of Columbus and 98 miles northeast of Cincinnati.

The cantonment is rectangular, half a mile wide and about 2 miles long, and lies in a bend of the river, which for 15 or 20 miles follows a serpentine course. It is in one of these curves that the camp is placed. The barracks and officers' quarters are completed, and most of them are heated.

DISEASE INCIDENCE

There have been about forty cases of pneumonia, but no epidemic. In the second increment of the draft a patient with acute tonsillitis arrived, and before isolation was effective there were thirteen cases; the next day there were eighteen cases and on the third day eleven cases; from then on the epidemic subsided to nine cases, then three, and after the sixth day no other cases appeared. The rapid development of these cases and the prompt subsidence of the epidemic prove the infectious nature of the process and warrant immediate and vigorous action when such cases appear in groups of men. There were eight cases of Vincent's angina, but they yielded promptly to local treatment. One case of epidemic meningitis showed the immediate effects of the injection of Flexner's serum, 400 c.c. of which were injected, partly by the intravenous and partly by the intraspinal route. All contacts were isolated and throat cultures were negative. In the city of Chillicothe there have been sixteen cases of smallpox, but none in the camp. Every draft or enlisted man before his physical examination is completed is vaccinated. The inoculations against typhoid and paratyphoid A and B have been followed by the usual reactions, but there were none of unusual severity.

PERSONAL

First Lieutenant Brainard from the Infantry School of Arms, Fort Sill, Okla., is in charge of the instruction in methods of gas defense and the treatment of gas casualties.

The Ross County Academy of Medicine, October 10, gave a delightful entertainment for the medical officers of the camp. It was well attended, and the president, Dr. F. T. Marr, made a cordial address of welcome which was responded to by Lieut.-Col. Wallace De Witt, the division surgeon. The county societies and the local medical societies as well as the druggists have arranged a plan of cooperation for the improvement of the sanitary conditions of the city and county which should prove of the greatest value and yield excellent results.

The campaign for the Second Liberty Loan obtained the total subscription of over $2,000,000 from the division.

The medical and sanitary problems are in the care of the division surgeon, Lieut.-Col. Wallace De Witt, M. C., U. S. Army, who has been four years at Fort Ethan Allen, Vt., and for two summers in charge of the training camps at Plattsburg, N. Y. Major John A. Burket, M. C., is in charge of the sanitation. Capt. Robert H. Halsey, M. R. C., is assistant division surgeon.

The base hospital, with a capacity of 1,000 beds, is under the command of Major Edward G. Huber, M. C. Major Christian R. Holmes of Cincinnati is chief of the otolaryngologic service. Major Casey A. Wood, M. R. C., of Chicago is chief of the ophthalmologic section. Major James A. Harvey, M. R. C., is chief of the surgical service. Major Dudley DeV. Roberts, M. R. C., is chief of the medical service. Captain Stanley M. Rinehart, M. R. C., is special examiner in tuberculosis. Capts. Henry L. Stick, M. R. C., Elmore E. Adel, M. R. C., and Charles W. Hoyt, M. R. C., are among those doing special work.

First Lieut. Benjamin H. Sherrard, Dental Corps, is directing the work of the dentists, of whom there are about forty-five in the cantonment.

The sanitary train is under the direction of Major Henry S. Satterlee, M. R. C. Major John R. McDowell, M. R. C., commands the ambulance companies. The field hospitals are well organized and almost completely equipped.

That the general health of the camp is excellent is shown by the noneffective rate, which is 14 per thousand.

Eighty-Sixth Division, Camp Custer, Battle Creek, Mich.

Preparations are being made through all regimental sanitary detachments to systematize the work of examining the remaining draft increment that is due to arrive almost any day. This will represent 55 per cent. of the original draft. With the experience gained through the examinations of those already here, there is no doubt that the large number expected will be run through with rapidity and precision. It is expected that there will be fewer discharges on account of physical disability than among the first examined, owing to the fact that the examining boards in the draft districts will be more thoroughly trained through the experience they have already had. The division surgeon has outlined plans which, when carried out, should make it possible for every medical officer to gain some experience in this form of examination and some practical knowledge of the paper work necessary in making out reports for acceptance and for discharge. Changes which are contemplated following an outlined course of instructions as suggested by Colonel Munson, U. S. M. C., will cause a general mix-up of all medical officers for the purpose of instructing them in the necessary detailed work of every medical organization in the division. Field hospital and ambulance company officers and enlisted men will be changed to regimental detachments, regimental detachment officers and enlisted men to field hospitals and ambulance companies, thus making it possible for every medical officer to become familiar with the work of the various organizations, making for greater efficiency in every department. Courses of lectures by line officers and experts in military hygiene, sanitation and the various medical and surgical specialties will be given and must be attended by all medical officers. This is not done with the view of making specialists of medical officers, yet it is very necessary that the medical personnel be thoroughly trained in all branches represented by these courses of instruction.

The Calhoun Medical Society of Battle Creek met Tuesday evening, November 6. Major Roy Bishop Canfield read a paper entitled "Consideration of Some Types of Sepsis and Their Results." Major Ernest Edward Irons read a paper entitled "Chronic Muscular and Articular Rheumatism: Treatment as Based on Etiology." These papers were discussed both by the civilian physicians and the members of the Medical Department, who were present in large numbers.

SANITARY TRAIN

The weather conditions have improved so that outdoor work has been progressing rapidly. Long hikes with maneuvers are daily occurrences. The men relish the change, as lecture work and indoor drills were becoming very tiresome.

Ambulance Company No. 340 gave a large banquet to the officers of the company Tuesday evening, November 6. Invited guests were Major E. C. Jackson, director of ambulance companies; Major Lewis Wine Bremerman, director of field hospitals, and Capt. C. J. MacGuire of Ambulance Company No. 337. Home talent was utilized, and a very enjoyable evening was the result.

Athletes are numerous in the sanitary train. The ambulance companies have developed an extraordinarily fine football team. They have been coached by Capt. H. H. Varner, commanding Ambulance Company No. 340, late coach of the University of Virginia. The team has been unbeaten this season, and has challenged any football team from any sanitary train in training at the present time.

BASE HOSPITAL

The base hospital is nearing completion, and in a short time will be in a position to carry out all its work in a normal manner. Major Wood, commanding, is to be congratulated on the manner of conducting the work there to date, handicapped as he has been by cramped quarters, inclement weather, incomplete heating arrangements, and other difficulties. All patients have been given fine care, and there has been no complaint from any quarter.

Eighty-Ninth Division, Camp Funston, Fort Riley, Kan.

This camp was originally planned for one infantry division and one depot brigade. Now, however, there are really three divisions: the eighty-ninth, white; the ninety-second, colored, and the depot brigade, while the division surgeon's office, therefore, is practically handling the work of an army corps. Nevertheless, the work of examining the men of the National Army has been done quickly and smoothly. It has been so systematized that one examining board has frequently examined over a thousand men in a day, including the administering of smallpox vaccine and the initial dose of the typhoid and paratyphoid prophylaxis.

A training officer, Medical Department, has been appointed for the Eighty-Ninth Division, and a schedule of instruction for the officers and men of the Medical Department has been instituted. Special subjects pertaining to work of the line are given in nightly lyceum lectures, by special officers of the departments concerned. The medical subjects necessary for the instruction of the enlisted personnel are taught by medical officers of the various organizations to which these men belong.

Col. Frank W. Weed, M. C., is sanitary inspector of the Eighty-Ninth Division. Major J. M. White, M. R. C., of St. Paul, is sanitary inspector of the Ninety-Second Division. Capt. R. B. Irones, M. R. C., of San Diego, Calif., is instructor in gas defense for the Eighty-Ninth Division.

The base hospital of Camp Funston is located at Fort Riley, 4 miles away. Patients, and clothing to be fumigated, are taken there and returned by ambulances over the new government macadamized road. A simple system of paper work has been instituted for these transfers, and no confusion results. At present, out of the whole command, there are approximately 30 cases of measles, 25 cases of cerebrospinal meningitis, 35 of mumps, 2 of scarlet fever and 50 of lobar pneumonia. No serious accidents have occurred, the worst being the loss of three fingers by a private who was fashioning a wooden rifle with an ax.

VENEREAL DISEASE

In civil life we have all heard of the great frequency of venereal diseases among soldiers of the Regular Army. In view of this teaching, it may be of interest to note our experiences in the examination of the National Army men just out of civil life on their arrival in camp. For the white troops the incidence of all venereal diseases has ranged between 5 and 6 per cent.; for the colored troops, over 20 per cent. These are all cases contracted prior to enlistment. At the time of present writing, no case has been reported that has been contracted since entering the military service in the Eighty-Ninth Division, which should furnish food for thought.

TYPHOID VACCINATION

A number of officers and men had received their typhoid prophylaxis prior to the order which made paratyphoid vaccination likewise compulsory. These men have subsequently had to take the three doses of paratyphoid A and B vaccine, whereas the men of the National Army have received only the three doses of U. S. triple vaccine, which consists of the paratyphoid and typhoid vaccines combined. It has been an experience common to the medical men of the camp that the reaction from the inoculation of paratyphoid vaccine, alone, has been much more severe than that of the triple vaccine or of the typhoid vaccine, alone. So far, no explanation has been attempted.

"SOB LETTERS"

An unpleasant phase of a medical officer's life is the "sob letters." Dozens of these, in tenor all alike, came through here every week. Anxious mothers, overzealous wives, and even mere acquaintances flood us with affidavits and letters about the physical condition of some of the men brought here by the draft. Some of these letters are extremely sad, others are absurdly funny, but all alike are given full consideration, which means a reexamination of the person referred to, by the already overworked surgeon. These letters rarely amount to anything, as the men unfit for service have already been weeded out as nearly as is humanly possible by the surgeons of the organizations to which they are attached, or by the Camp Board of Special Examiners.

PERSONAL

Capt. Bruce Ffoulkes, M. R. C., has been made director of field hospital companies, and Lieut. John D. Bartlett, M. R. C., has been made director of ambulance companies, of the Three Hundred and Fourteenth Sanitary Train, Eighty-Ninth Division. Lieut.-Col. Harry L. Boyer, M. C., has been appointed division surgeon of the Ninety-Second Division, and Captain Nicholls, M. R. C., formerly of the Presbyterian Hospital in Chicago, has been made his assistant. Lieut. Louis G. Harney, M. R. C., of wide industrial medical experience with the American Steel Foundries of East St. Louis, is assistant to the division surgeon of the Eighty-Ninth Division. Lieut. Judd H. Kirkham, M. R. C., of Langdon, N. D., is attending surgeon of the headquarters, Eighty-Ninth Division. Lieut. Albert G. Bower, M. R. C., formerly of the Department of Bacteriology, University of Chicago, is medical training officer of the Eighty-Ninth Division.

DISEASE CONDITIONS AMONG TROOPS IN THE UNITED STATES

Extracts from Telegraphic Reports Received in the Office of the Surgeon-General for the Week Ending Nov. 2, 1917

1. Total strength of troops		1,001,632
Admission rate per 1,000 (disease only)	annual	955.2
Non-effective rate (all causes)		25.6
2. National Guard, strength		373,180
Admission rate per 1,000 all camps (disease only)	annual	1,108.8
Non-effective rate all camps (all causes)		24.5

Camps showing admission rate for disease higher than average: Camps Kearney, Wheeler, Cody, Bowie, Sevier, Beauregard and Shelby.

Camps showing noneffective rate higher than average: Camps Wheeler, Bowie, Logan, MacArthur, Shelby, Beauregard, Sevier, Cody, Hancock and Kearney.

3. National Army, strength		426,578
Admission rate per 1,000 all camps (disease only) annual		929.8
Non-effective rate all camps (all causes)		20.1

Camps showing admission rate for disease higher than average: Camps Pike, Jackson, Dix, Dodge, Travis, Funston, Gordon and Lewis.

Camps showing noneffective rate all causes higher than average: Camps Pike, Dodge, Funston, Lewis and Dix.

4. Venereal Disease—

Admission rate Regulars		90.4
Admission rate National Guard (camps)		93.6
Admission rate National Army		135.6

Camps National Guard having rate above average: Camps Sheridan, Wheeler, Kearney, Logan, Sevier, MacArthur and Bowie.

Camps National Army having rate above average: Jackson, Pike, Custer, Dix, Lee, Travis and Meade.

5. Number of cases of pneumonia		228
Highest number in any one camp	Funston	22
Number of cases of meningitis		18
Highest number in any one camp	Funston	9

	Regulars, U. S. Army, in U. S. only, 1916		Regulars in U. S. week ending Nov. 2, 1917		Nat'l Guard, All Camps, week ending Nov. 2, 1917		Nat'l Army, All Camps, week ending Nov. 2, 1917

ORDERS TO OFFICERS OF THE MEDICAL CORPS

To report to Board for examination for promotion: Col. HENRY D. SNYDER, Washington, D. C.; Majors WILLIAM K. BARTLETT, Takoma Park, D. C.; WILLIAM A. DUNCAN, Washington, D. C.; and PAUL L. FREEMAN, Fort Myer, Va.

Major HERBERT C. GIBNER, now on duty in the Hawaiian Department *to report to board* convened by the commanding general, Hawaiian Department, *for examination for promotion.*

Col. ALBERT E. TRUBY, now on duty in the Panama Canal Department, *to report to board* convened by commanding general, Panama Department, *for examination for promotion.*

To report to board convened by commanding general, American Expeditionary Force, France, *for promotion,* Col. JAMES R. CHURCH; Lieut.-Cols. CHARLES L. FOSTER, JAMES D. HEYSINGER and JOSEPH F. SILER; Majors LUCIUS L. HOPWOOD, HENRY J. NICHOLS, OMAR W. PINKSTON, GUY V. RUKKE, ROBERT M. CULLER, CLEMENS W. McMILLAN, ARTHUR N. TASKER, and H. VAN KIRK.

To report to board convened by commanding general, Western Department, *for promotion,* Col. ELMER A. DEAN, San Francisco, Calif.; Lieut.-Col. WILLIAM H. TEFFT, Fort Douglas, Utah; and Major WILLIAM R. DAVIS, Fort Rosecrans, Calif.

To report to board convened by commanding general, Central Department, *for promotion,* Cols. PERCY M. ASHBURN, Fort Benjamin Harrison, Ind., and HENRY S. GREENLEAF, Fort Snelling, Minn.; Lieut.-Cols. HENRY F. PIPES, and GIDEON McD. VAN POOLE, Fort Benjamin Harrison; Majors HENRY C. PILLSBURY and FRANK W. WEED, Fort Riley, Kan., HOWARD H. BAILY, Camp Grant, Rockford Ill., WILLIAM A. WICKLING, St. Louis, Mo., and WILLIAM S. SHIELDS, Chicago, Ill.

To report to board convened by commanding general Eastern Department, *for promotion,* Col. FRANCIS M. C. USHER, Fort Slocum, N. Y.; Lieut.-Cols. ORVILLE G. BROWN, Camp Mills, Garden City, L. I., N. Y., JOHN R. BOSLEY, Fort Ontario, N. Y., SAMUEL M. DeLOFFRE, Plattsburg Barracks, N. Y., GEORGE F. JUENEMANN, Gettysburg, Pa., and HENRY D. THOMASON, Fort Ontario, N. Y.; Majors LOUIS H. HANSON, Syracuse, N. Y.; HARRY G. HUMPHREYS, Fort Hancock, N. J.; FREDERICK S. MACY, Fort Jay, N. Y., FERDINAND SCHMITTER, Camp Lee, Petersburg, Va.; WILLIAM C. DAVIS, Camp Dix, Wrightstown, N. J., CHARLES L. GANDY, Allentown, Pa., PAUL W. GIBSON, N. Y. C., EDGAR C. JONES, Newport News, Va., and WILLIAM W. VAUGHAN, Allentown, Pa.

To report to board convened by commanding general, Southern Department, *for promotion,* Lieut.-Cols. WILLIAM P. BANTA, Nogales, Ariz., ROBERT L. CARSWELL, Fort Sam Houston, Tex., and ROBERT C. LOVING, San Antonio, Tex.; Majors CLARENCE L. COLE, Fort Sam Houston, Tex., and EIDE F. THODE, Fort Clark, Tex.

To report to board convened by commanding general, Southeastern Department *for promotion:* Lieut.-Cols. CRAIG R. SNYDER, Camp McClellan, Anniston, Ala., and ARTHUR M. WHALEY, Camp Sevier, Greenville, S. C.; Majors CHARLES E. FREEMAN, Camp Pike, Little Rock, Ark., and LEARTUS J. OWEN, Camp Greenleaf, Fort Oglethorpe, Ga.; Lieut.-Col. LOUIS C. DUNCAN, Fort McPherson, Ga., Majors CHARLES W. HAVERKAMPF, Fort Oglethorpe, Ga., and EDWARDS C. REGISTER, Hot Springs, Ark.

To report to board of commanding general, Northeastern Department, *for promotion,* from Camp Devens, Ayer, Mass., Northeastern Department, Major GLENN I. JONES.

Colonel WILLIAM OWEN, to attend meeting of Southern Medical Association, Memphis, Tennessee, Nov. 12 to 16, 1917.

Colonel WILLIAM F. LEWIS, now on duty at San Antonio, Texas, to proceed to the following named places, for the purpose of making special sanitary inspections, and on completion of duty, to return to station: *Waco, Texas,* The Aviation Camp and Camp McArthur; *Fort Worth, Texas,* The Aviation Camp and Camp Bowie; *Dallas, Texas,* The Aviation Camp; *Wichita Falls, Texas,* The Aviation Camp; *Fort Sill, Okla.,* The Aviation Camp and Camp Doniphan; *Houston, Texas,* the Aviation Camp and Camp Logan.

Colonel EDWARD L. MUNSON, *to Roanoke, Va.,* to address Medical Society of Virginia on recruiting and training of medical officers.

Lieut.-Col. CHARLES F. MORSE, relieved from duty at Fort Benjamin Harrison, Ind., and *to proceed to Washington, D. C.,* and report to the Surgeon-General of the Army for duty in his office.

Major EDGAR KING *to Goshen, Va.,* to inspect property under consideration to be used as a general hospital, and on completion of duty to return to station.

Colonel ALLEN M. SMITH, now on duty at Fort Logan, Colo., *to Grand Junction, Colo.,* to report on the suitability and availability of the former United States Teller Institute for use as a general hospital, and on completion of duty to return to station.

Major GLENN I. JONES, *now on duty at* Camp Devens, Ayer, Mass., *to Washington, D. C.,* and report in person to the Surgeon-General for conference, and on the completion of duty, to return to station.

Major THOMAS D. WOODSON, to the following-named places to determine their suitability for general hospital purposes and inspecting sites for other general hospital purposes: *Stockbridge, Mass.; Worcester, Mass.; Boston, Mass.,* and on completion of the duty at Boston, Mass., to proceed to the following-named places for the purpose of inspecting sites offered for general hospital purposes, and upon completion of this duty to return to his proper station: *Willets Point,* New York; *Camp Mills,* Garden City, L. I., N. Y.; *Iselin,* New Jersey.

Lieut.-Col. WILLIAM H. MONCRIEF, *to New York City*, for temporary duty at the Rockefeller Institute and on completion of duty to return to station.

Major ROBERT H. DUENNER, to be relieved from duty in the Hawaiian Dept. and directed *to proceed to the United States*, and on arrival *to Fort Riley, Kan.*, to organize and command Hospital Train No. 25.

Major STEPHEN H. SMITH, relieved from duty at Schofield Barracks, Hawaii, and *to Fort Oglethorpe, Ga.*, to organize and command Hospital Train No. 23.

Lieut.-Col. WILLIAM C. BORDEN, U. S. Army, Retired, *to Rockefeller Institute* for a course of instruction, and on completion of duty to return to station, Walter Reed General Hospital, Takoma Park, D. C.

Major SAMUEL J. TURNBULL relieved at Fort Benjamin Harrison, Ind., and *to Fort Riley, Kan.*, and report in person to the commandant, to organize and command Hospital Train No. 24.

Lieut.-Col. THEODORE LAMSON, relieved from duty with Field Hospital No. 3, Fort Oglethorpe, Ga., and *to commandant Camp Greenleaf*, for temporary duty.

Major WILLIAM B. MEISTER relieved from duty at the Presidio of San Francisco, Calif., and *to Fort Oglethorpe, Ga.*, to organize and command Hospital Train No. 28.

Major THOMAS L. FERANBAUGH relieved from duty at Laredo, Texas, and *to Fort Worth, Texas*, Camp Bowie, to command base hospital.

Major GEORGE E. PARISEAU, relieved from duty as commanding officer of the base hospital at Camp Bowie, and *to Fort Oglethorpe*, for duty with Field Hospital No. 3.

Colonel IRVING W. RAND, relieved from duty at the Philippine Dept., Tientsin, China, and *to San Francisco, Calif.*, and report in person to the commanding general, Western Department, for duty.

Colonel HENRY A. SHAW, *to Petersburg, Va.*, Camp Lee, for duty in connection with psychologic examinations, and on completion of duty to return to station.

Major ROBERT M. HARDAWAY, relieved at Fort Bliss, and *to Fort Oglethorpe, Ga.*, to organize and command Hospital Train No. 22.

Major WILLIAM R. DEAR, relieved from Philippine Department and *to Fort Oglethorpe, Ga.*, to organize and command Hospital Train No. 27.

Major WILLIAM D. HERBERT, relieved from Philippine Dept. and *to Fort Oglethorpe, Ga.*, to organize and command Hospital Train No. 26.

Lieut.-Col. CHARLES F. MORSE, now at the medical officers' training camp, Fort Benjamin Harrison, Ind., under orders to report to the Surgeon-General's office, to proceed to the following-named camps for the purpose of inspecting the base hospital thereat, and on completion of this duty to comply with previous orders directing him to proceed to Washington, D. C., *Camp Sherman*, Chillicothe, Ohio; *Camp Custer*, Battle Creek, Mich.

Lieut. FRANK L. COLE, relieved from Allentown, Pa., and *to Army Medical School*, for instruction in orthopedic surgery.

ORDERS TO OFFICERS OF THE MEDICAL RESERVE CORPS

Alabama

To Camp Greenleaf, Fort Oglethorpe, for a course of instruction, Lieut. LEROY H. WOODRUFF, Anniston.

To Camp Kelly, San Antonio, Texas, for duty, from Fort Oglethorpe, Lieut. ROSCOE C. STEWART, Wylam.

To Camp Lee, Petersburg, Va., for duty, from Army Medical School, Lieut. HARRY P. SHURGERMAN, Birmingham.

To Camp Logan, Houston, Texas, for temporary duty in the base hospital, from Fort Oglethorpe, Lieut. JAMES D. PERDUE, Furman.

To Fort Oglethorpe, for a course of instruction, Lieut. MILES A. WATKINS, Birmingham.

To Newport News, Va., Port of Embarkation, for duty, Capt. MACK ROGERS, Birmingham.

To Philadelphia, University Hospital, for a course of instruction on fractures, and on completion of this course to proceed to Camp McClellan, Anniston, Ala., for temporary duty in the base hospital, Lieut. WILLIAM W. BURNS, Selma.

To his home and to the inactive list of the Medical Reserve Corps on account of being physically disqualified for active service, Lieut. JACOB D. STAPLES, Camp Hugh.

Arizona

To New York City, for orthopedic instruction, Capt. CHARLES T. STURGEON, Globe.

Arkansas

To Army Medical School, Washington, D. C., for a course of instruction, Lieut. JOHN F. LIEBERMAN, Pine Bluff.

To Camp Devens, Ayer, Mass., for duty, from Army Medical School, Capt. HARRY H. TOWLER, Fayetteville.

To New York City, Cornell Medical College, for a course of instruction in military roentgenology, from Fort Benjamin Harrison, Lieut. RAY B. THOMAS, Enosburg.

Virginia

To Camp Greenleaf, Fort Oglethorpe, for a course of instruction, from *School of Plastic and Oral Surgery,* Washington University, St. Louis, Lieut. DORSEY C. TYLER, Richmond.

To Camp Joseph E. Johnston, Jacksonville, Fla., for duty from Fort Oglethorpe, Lieut. HORACE T. HAWKINS, Richmond.

To Camp Kelly, San Antonio, Texas, for duty, from Fort Oglethorpe, Lieut. FRANK A. FARMER, Roanoke.

To Camp Lee, Petersburg, Va., for duty, Lieut. GROVER B. GILL, Tangier; *for duty with the auxiliary remount station, from Camp Lee,* Lieut. WILLIAM P. MERCHAUT, Manassas.

To Camp Meade, Annapolis Junction, Seventy-Ninth Division, for duty, from Fort Oglethorpe, Lieut. JAMES S. BURGER, Hopewell.

To Camp Pike, Little Rock, Ark., for duty as a member of a board for the special examination of the command for tuberculosis, from Camp Joseph E. Johnston, Lieut. HORACE T. HAWKINS, *Richmond.*

To Fort Oglethorpe, for a course of instruction, Lieut. GEORGE V. LITCHFIELD, Abington.

To Newport News, Va., for duty at the Port of Embarkation, Lieut. LONSDALE J. ROPER, Portsmouth.

To Staunton, Va., for the purpose of examining applicants for appointments in the Medical Reserve Corps, and on completion of this duty to return to his proper station, from Richmond, Major JOHN G. NELSON, Richmond; JOSEPH T. McKINNEY, Richmond.

To Walter Reed General Hospital, Takoma Park, D. C., for a special course of instruction *in tuberculosis examination,* Lieut. THOMAS N. DAVIS, Lynchburg.

To Washington, D. C., and report in person to the *Surgeon-General* of the Army for temporary duty in *his office, from Fort Randolph, C. Z.,* Lieut. EDGAR A. BOCOCK, *Richmond; to Army Medical School, for* a course of instruction, Lieut. HARVEY R. LIVESAY.

Washington

To Camp Lewis, American Lake, Washington, for duty in the base hospital, to be relieved of his present duties, Capt. ERNEST C. WHEELER, Tacoma.

To Fort Mackenzie, Wyo., for duty from Camp Dodge, Capt. JOHN B. ROBERTSON, Tacoma.

West Virginia

To Army Medical School, Washington, D. C., for a course of instruction, Lieuts. ARTHUR N. HENSON, LAWRENCE A. PETTY, Charleston.

To Walter Reed General Hospital, Takoma Park, D. C., for a special course *of instruction* in tuberculosis examinations, Capts. GEORGE H. BARKSDALE, JOHN W. MOORE, Charleston; Lieut. DAVID P. SCOTT, Ashland.

To his home and the inactive list of the Medical Reserve Corps on account of being physically disqualified for active service, from Fort Oglethorpe, Lieut. ROBERT K. BUFORD, Princeton.

Wisconsin

To Camp Custer, Battle Creek, Mich., Twenty-Fifth *Division, for duty,* Lieut. WILLIAM C. HANSON, *Racine.*

To Camp Jackson, Columbia, S. C., for duty as a member of a board of medical officers for the special examination of the command for tuberculosis, from Fort Oglethorpe, Lieut. LEON H. FLANCHER, Milwaukee.

To Fort Bliss, Texas, for temporary duty, from Fort Riley, Lieut. ADDISON J. PROVOST, Oshkosh.

To Fort Oglethorpe, for a course of instruction, Lieut. HERMAN A. HEISS, Madison.

To New York City, Cornell Medical College, for a course of instruction in military roentgenology, from Fort Oglethorpe, Lieut. HARRY B. PODLASKY, Milwaukee.

To his home and the inactive list of the Medical Reserve Corps, from Washington University, St. Louis, Capt. GUSTAF R. EGELUND, Sturgeon Bay; from Camp Doniphan, Lieut. GEORGE G. RUHLAND, Milwaukee.

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest; such as relate to society activities, new hospitals, education, public health, etc.)

CALIFORNIA

Personal.—Dr. Nolton N. Ashley, chief of the staff of the Oakland Emergency Hospital, has resigned, and has been succeeded by Dr. Charles H. Mackey.——Drs. Henry G. Brainerd, Charles L. Allen, Thomas J. Orbison and Edward H. Williams, all of Los Angeles, are the medical members of the board of trustees of the Psychopathic Association of California, elected at its annual meeting in Los Angeles, October 22.

Anthrax.—During August and September, according to the *Monthly Bulletin* of the state board of health there were eight human cases of anthrax in the state as reported to the board, and the state veterinarian has called attention to outbreaks among animals in Yolo, San Joaquin and Stanislaus counties and in remote sections of the San Joaquin and Sacramento valleys. In Yolo for a period the water in irrigating ditches was ordered shut off to prevent the possible spread of the disease by that means. Warnings have been given in regard to the handling of sick stock and the skinning of dead animals.

COLORADO

Personal.—Dr. Raynor E. Holmes, Canon City, has purchased the Goodloe Hospital, with a capacity of twenty beds, and will conduct it as a private hospital.—Drs. Wilbur T. Little and Hart Goodloe have entered on their military duties at Fort Sill, Okla., and Fort Riley, Kan., respectively.——Dr. Frederick A. Jackson, Salida, has been appointed physician and deputy coroner of Chaffee County, during the absence of Dr. Charles S. Phalen.——Dr. George B. Gilmore has been appointed assistant health officer for West Colorado Springs.

DELAWARE

Personal.—Dr. William P. Orr, Lewes, has been placed in command of the Marine Hospital at Lewes, succeeding Dr. George G. Hart, transferred.——Dr. John W. Mullin, Wilmington, has been appointed chief of the medical staff of the Delaware Hospital.

Typhoid Fever.—October 26, there were twenty-nine cases of typhoid fever in Wilmington which are known to have originated outside of that city. In addition, there are twenty cases which have been traced to one source in Wilmington. The supply of drinking water of the city is reported to be sanitary.

ILLINOIS

Personal.—Dr. Edward A. Glasgow was elected president of the First National Bank of Mulberry Grove, November 5.——Dr. Edgar P. Cook, Mendota, has been appointed chairman of the cooperative committee to promote the antituberculosis campaign of the State Council of Defense.

Assignments to Health Officers.—The state director of health, Dr. C. St. Clair Drake, Springfield, announces the following assignments:

Dr. Clarence W. East, Evanston, relieved as medical officer for Camp Grant Health District, and detailed to investigate poliomyelitis in Cook County, and afterward to report for special assignment.

Dr. Arthur Pearman, Rockford, medical health officer to Camp Grant Health District, Rockford.

Dr. Alexander F. Stewart, Oneida, district health officer for the Western Health District, with headquarters at Galesburg.

Dr. John A. Kappelman, Evanston, relieved as medical health officer of Great Lakes-Fort Sheridan Health District excepting special assignment relating to water supply and sewerage disposal problems in North Chicago and Waukegan, and garbage disposal at Lake Bluff and Lake Forest, and detailed as health officer of the Northeast Health District, with headquarters at Chicago.

Dr. John A. Robison, Chicago, medical health officer of Great Lakes-Fort Sheridan Health District, with temporary headquarters at Lake Forest.

Dr. Charles E. Crawford, Rockford, medical health officer of the Northwest Health District excepting temporarily the Camp Grant District, with headquarters at Rockford.

Dr. Edward M. Irwin, Belleville, medical health officer for the Scott Field Health District, including the towns of Shiloh Valley and Belleville, in St. Clair County.

Dr. Charles S. Nelson, Springfield, medical health officer of the North Central Health District, with headquarters at Springfield.

Dr. Elbert L. Damron, Effingham, district health officer for the South Central Health District, with headquarters at Effingham.

Dr. John A. M. Gibbs, Unity, medical health officer for the Southern Health District, succeeding Dr. Isaac A. Foster, New Haven.

Chicago

Children's Hospital Profits by Rummage Sale.—As a result of the four days' White Elephant Sale, held in the old Calumet Club Building, November 7 to 10, $25,369 was raised for the Children's Memorial Hospital.

Personal.—Dr. Daniel N. Eisendrath read a paper on "Why Do We Have Recurrence of Symptoms After Operations on the Biliary Tract?" at the annual meeting of the Wisconsin State Medical Society, held in Milwaukee, October 3, and also read a paper on the same subject at the annual meeting of the Southern Illinois Medical Association, held at Murphysboro, November 1.

INDIANA

Tuberculosis Hospital Site.—The Madison County Council has appropriated $10,000 for the purchase of the site for a county tuberculosis sanatorium. A farm of 92 acres near Anderson has been selected for this purpose.

Endorse Wynn's Candidacy.—The Indianapolis Medical Society, October 27, adopted a resolution endorsing the candidacy of Dr. Frank B. Wynn for a member of the board of school commissioners, and paying high tribute to the ability and attainments of Dr. Wynn.

Personal.—Dr. Henry Jameson, Indianapolis, fuel administrator for Marion County, is the first director whose appointment has been formally recorded by the state administrator.——Major Orange G. Pfaff, Indianapolis, will not be able to accompany Base Hospital Unit No. 32, on account of an injury to his knee.

IOWA

Honor to Rosenow.—At a gathering of representative citizens of Davenport, November 9, honor was rendered to Dr. E. C. Rosenow, in appreciation of his assistance during the recent epidemic of infantile paralysis in Davenport. An inscribed scroll stating the appreciation of his work, signed by the mayor and representatives of civic, social and medical organizations, was presented to Dr. Rosenow.

KENTUCKY

Personal.—Dr. Thomas F. Cleaver, Lebanon, sustained painful injuries when an engine ran into his automobile on a grade crossing, October 19.——Dr. John W. Gilbert, Lawrenceburg, while burning charcoal in a cistern, was overcome by the gas, and managed to get out of the cistern, but fell, sustaining painful wounds of the forehead.

MAINE

Health Department Reorganized.—The old state board of health, which was created in 1885, has been superseded by the state department of health, which was created by an act passed by the seventy-eighth legislature. Dr. Leverett D. Bristol has been appointed commissioner of health, and the state has been divided into health districts, each in charge of a district health officer.

Health Council.—The governor has nominated the following as the new Maine health council: John J. Ryan, Lewiston, probation officer; Eugene A. Cloutier, Lewiston, associate probation officer; Mrs. George F. French, Portland; Drs. Joseph E. Odiorne, North Whitefield; Robert J. Aley, Orono; Hiram W. Ricker, Poland; Sylvester J. Beach, Augusta, and Joseph B. Drummond, Portland.

MASSACHUSETTS

Personal.—Dr. Joseph A. Smith, police surgeon of Worcester, has resigned to enter the army service.——Physicians of Haverhill visted Georgetown, October 22, to pay their respects to Dr. Richmond B. Root, who celebrated the fiftieth anniversary of his entrance into the practice of medicine on that day.

Orthopedic Hospital for Boston.—The Order of Elks has made an offer to the city council of Boston to erect, for the federal government, an orthopedic hospital to cost $250,000, on the site of the old Parker Hill reservoir, provided the city will sell the site for $40,000. This is expected to be the first reconstruction hospital in the United States for crippled soldiers and sailors.

MICHIGAN

Tuberculosis Foes Meet.—At the annual meeting of the Michigan Anti-Tuberculosis Association, held in Battle Creek, Dr. William De Kleinie, Flint, was elected president, Drs. John H. Kellogg, Battle Creek, and Christopher G. Parnall, Jackson, vice presidents, and Dr. Henry J. Hartz, Detroit, secretary.

Personal.—Dr. William F. English, Saginaw, a member of the state board of health, will be stationed permanently at Battle Creek to assist the military authorities and the state board of health in the campaign to protect the health and morals of the soldiers at Camp Custer.——The University of Michigan has accepted the resignation of Dr. Claudius B. Kinyon, Ann Arbor; for twenty years professor of obstetrics and gynecology in the Homeopathic Medical School, and has appointed Dr. Theron G. Yeomans, St. Joseph, his successor.

Antituberculosis Notes.—Muskegon, Ottawa and Allegan counties are considering the proposition to build and operate a cooperative tuberculosis sanatorium.——At the meeting of the Michigan Anti-Tuberculosis Society, October 30, it was recommended that the state establish sanatoriums for men rejected from the National Army on account of tuberculosis who could be restored to health.——It is proposed to erect a joint tuberculosis sanatorium, to cost about $100,000, for the use of the six counties of Oakland, St. Clair, Livingston, Macomb, Washtenaw and Lapeer.——Members of the Delta County Board of Supervisors have approved the establishment of a joint tuberculosis society with Menominee, Dickinson and Iron counties.

MINNESOTA

Smallpox at Hamline.—There are now five cases of smallpox at Hamline University, Minneapolis. Practically all the students have been vaccinated.

Faculty and War Work.—Fifteen men and two women of the University of Minnesota faculty have been granted leave of absence by the board of regents to engage in war work for the government.

Navy Hospital School Opened.—October 29, the Navy Hospital Corps Training School of the University of Minnesota was formally opened, with an initial attendance of 100 Hospital Corps men from the Navy. The staff is supplied by the University of Minnesota Medical School.

Personal.—Dr. Jacob H. Stewart, St. Paul, was found unconscious on Summitt Avenue, St. Paul, November 1. He had apparently suffered a slight concussion of the brain.——Dean T. Frankforter of the College of Chemistry of the University of Minnesota was relieved of his administrative duties at his own request, October 25, and reduced to the rank of professor.——Drs. Clarence E. Lum, Duluth, and Walter Courtney, Brainerd, were severely injured by falling through a trap door at a hunting lodge in Ottertail County, October 25.——Dr. Walter R. Ramsey, St. Paul, will head a medical mission to France in January. Dr. Ramsey will take the place of Dr. Julius P. Sedgwick of the university, who is now in France organizing the work among children in the fighting zone.

MISSOURI

Tuberculosis Ward Opened.—The entire north wing on the fourth floor of the Kansas City General Hospital, which was formerly occupied as nurses' headquarters, is being remodeled, and will be used as a tuberculosis ward, accommodating about sixty-five patients.

Personal.—Dr. George P. Pipkin, Kansas City, who has been in Colorado for the past five months in search of health, has returned greatly improved.——Dr. Louis E. Newman, St. Louis, who had five ribs fractured in a collision between his automobile and a coal wagon, is reported to be convalescent.

Medical Inspection of Schoolchildren.—While medical inspection of the schoolchildren of Kansas City has been suspended by the municipal authorities for lack of funds, a public spirited citizen, who desires to remain incognito, has agreed to pay the expenses of the work for three months. Five physicians, five dentists and ten nurses will form the staff of inspectors and begin work at once under the supervision of the Hospital and Health Board.

Society Inaugurates Movement for Combining Laboratories of State Board of Health and State University.—At a recent meeting of the Boone County Medical Society, to which the members of Audrain, Gallaway, Cole, Cooper, Howard and Randolph County Medical Societies had been invited, resolutions were adopted in which were set forth the advantages of free laboratory work being done by the state university. It was proposed that the people of Missouri be made acquainted with the beneficial results of such a procedure, and that the next legislature be urgently requested to make the necessary appropriation for rendering the resolution effective.

First Class in Oral and Plastic Surgery Completes Course.—The first class of students from the Officers' Medical Reserve Corps ordered to take the course in oral and plastic surgery in the special school established at Washington University Medical School by the Surgeon-General of the Army has completed its course, the members, numbering thirty-seven, returning to their respective posts. The second contingent has reported for the course which began, November 5. There are thirty-five men in this class, of which twenty-seven are surgeons and eight are dentists. This course differs from the first in that it offers, in addition to oral and plastic surgery, surgery of the cranium and brain. Dr. Robert T. Frank, New York, is acting as military director.

Must Clean Up Vice Conditions.—Kansas City must clean up vice conditions at once or be quarantined against army camps is the edict of United States government officials. Mr. Henry F. Bart, in charge of the law enforcement department of the War Department, recently visited Kansas City and found conditions so demoralizing for the soldiers who visit the city from nearby camps that he ordered the immediate closing of all immoral houses, prohibiting women from soliciting on the street, and keeping all liquor away from soldiers. While the saloons have generally obeyed the law to refuse liquor to soldiers, the rooming houses and some hotels have permitted drinks to be served to soldiers in private rooms. The police department and the prosecuting attorney have promised to wipe out these vicious influences.

NEW HAMPSHIRE

Students Must Have Physical Examination.—The trustees of the New Hampshire College, Durham, have decided that hereafter every student on entering college must pass a physical examination.

Personal.—The residence of Capt. Charles A. Lamson, M. R. C., U. S. Army, at New London, was destroyed by fire, October 2.——Dr. Patrick J. McLaughlin, Nashua, has been appointed physician of Hillsboro County, succeeding Dr. Charles E. Congdon, who is in war service.

NEW JERSEY

Hospital Burns.—The Trenton Municipal Hospital, containing fifty-five patients, was burned, November 6. All the inmates escaped or were carried to places of safety, some of them being taken from the second floor by the staff of nurses, who for a times worked single handed in the mission of rescue. The loss is placed at $40,000.

Tri-County Physicians Elect Officers.—At the annual meeting of the Tri-County Medical Society, which includes, Cumberland, Salem and Gloucester counties, held at Millville, October 30, the following officers were elected: president, Dr. Harry A. Stout, Wenonah; vice presidents, Dr. Joseph N. Husted, Woodstown, and John H. Moore, Bridgeton, and secretary-treasurer, Dr. George E. Reading, Woodbury.

NEW YORK

Personal.—Dr. and Mrs. William N. Miller, Croton-on-Hudson, were seriously injured in a collision between their automobile and another car at Harmon-on-Hudson.——Dr. Marcus E. Babcock, Bath, was struck by an automobile, October 28, and received a severe wound of the scalp.——Dr. George F. Reusch, Franklinville, has accepted a position with the mining company at Virginia, Minn.

Commission Discusses Care of Insane.—The Hospital Development Commission, which was created by the last legislature to form a plan for the systematic enlargement of state institutions for the insane and feebleminded, recently conducted a hearing at the New York Academy of Medicine. The commission has presented the results of an investigation of the institutions for the care of the insane in this state and in Massachusetts, as well as in other states. The immediate establishment of psychopathic hospitals, especially in New York City, was urged. These hospitals should be employed simply as clearing houses to determine which persons might be restored by a short term of treatment and which should be sent to the state hospitals. The opinion was expressed that the care of the insane is properly a state function and should be kept so, as municipal governments were too likely to shift.

New York City

Woman Head of Parole Board.—Dr. Katherine B. Davis has been appointed chairman of the parole board by Mayor Mitchell. The term of office runs for ten years, with a salary of $7,500 a year.

Anniversary Address.—The anniversary address of the New York Academy of Medicine was delivered, November 15, by Dr. Henry Fairfield Osborn, L.L.D., president of the National Museum of National History, on "The Origin and Nature of Life."

Jamaica Hospital Opens Laboratory.—The Jamaica Hospital, Borough of Queens, announces that it has just completed the equipment of a roentgen-ray laboratory and is ready to render prompt and efficient service to the physicians of Queens who refer cases for roentgen-ray examination.

New York's Quota of Doctors for War Service.—The New York Chapter of the Red Cross has issued a statement asserting that when the base hospital units now awaiting a call to duty are in service, New York City will have sent 200 physicians and surgeons and more than 500 Red Cross nurses for war hospital work. The Presbyterian, Roosevelt, New York Post-Graduate, and the New York hospitals are already in service abroad. The other units, Bellevue, Mount Sinai, Herman and Metropolitan hospitals, have long been in readiness.

Medical Services Discuss War Problems.—Under the auspices of the New York State Committee, Medical Section of the Council of National Defense, a rally was held on the evening of November 9 at the Waldorf-Astoria, at which the heads of the medical services of the British and American governments discussed the probable requirements of the medical service. Dr. George D. Stewart presided at the meeting, and the principal addresses were made by Col. Sir Berkeley Moynihan, Major George W. Crile, Cleveland, and Dr. Franklin H. Martin, Chicago.

City Food Cabinet Organizes.—City Market Commissioner Henry Moschowitz has organized a cabinet of advisers drawn from the various city departments to consider the city's new undertaking of buying and selling food and fuel to the people. Work has been assigned to various city departments. The health department has as its task to make a study of wholesale and retail prices of essential commodities and the relation of these prices to the factors of distribution of trade. The Department of Public Charities is to study the relation of present prices to income. The members of this cabinet are to hold a conference each week to discuss ways and means of conducting their campaign to control, if possible, the high cost of living.

PENNSYLVANIA

Hospital Endowed.—The George F. Geisinger Memorial Hospital, Danville, built at a cost of $600,000 has now been endowed by Mrs. Geisinger for $1,000,000. A Scranton trust company has been named as trustee, the local board of trustees having been asked to resign.

Personal.—Dr. W. Rowland Davies, Scranton, has been elected president of the Craftmen's Club.——Dr. Adolph Koenig, Pittsburgh, October 1, was reappointed a member of the State Bureau of Medical Education and Licensure.——Dr. Adam L. Kotz, Easton, has resigned from the staff of St. Luke's Hospital, South Bethlehem, and has been appointed pathologist for the Easton Hospital.——Dr. Henry L. Orth, for twenty-seven years superintendent of the State Lunatic Hospital of Harrisburg, has resigned his position, to take effect as soon as his successor can be appointed.——Dr. Harvey L. Gerberich, Lebanon, was operated on in the Good Samaritan Hospital, in that city, and is reported to be convalescent.——Dr. Daniel Frederick, Ashley, who was operated on for appendicitis in St. Francis' Hospital, Pittsburgh, November 7, is reported to be doing well.

Philadelphia

Ambulance for Jefferson Base Hospital.—The West Philadelphia Auxiliary No. 4 of the American Red Cross presented a new field hospital ambulance to Base Hospital No. 38 of the Jefferson Medical College Hospital, November 7.

Reception to Moynihan and Crile.—At the stated meeting of the Club of Physicians in Philadelphia, November 7, the scientific business of the meeting was omitted on account of the reception to Sir Berkeley Moyihan, R. A. M. C., and Major George W. Crile, M. R. C., U. S. Army.

Plant Oak in Honor of White.—October 26, Arbor Day, in the presence of a notable group of representatives of business, professional and city life of Philadelphia, a red oak tree was planted in Rittenhouse Square in honor of the late Dr. William White, surgeon, author and nature lover.

Personal.—Dr. W. Wayne Babcock has been appointed chief surgeon of the base hospital at Fort McPherson, Atlanta, Ga.——Dr. Clarence P. Franklin, adjutant of the Allentown training camp, has been promoted from major to Lieutenant-Colonel.——Dr. Richard M. Pearce, professor of research medicine, University of Pennsylvania, has been made director of the recently established bureau of medical service of foreign commissions of the American Red Cross.——Dr. Edward A. Schumann has been elected lecturer on obstetrics in the Jefferson Medical College.——Dr. Mary D. Ridgeway, Germantown, was seriously burned, October 17, by the explosion of a lamp.——Dr. Hubley R. Owen has been given an indefinite leave of absence as chief of police surgeons of Philadelphia. Dr. Owen is an officer of the Medical Reserve Corps, and is connected with the Jefferson Hospital Unit.

School of Oral Surgery Opens.—November 10, Provost Smith of the University of Pennsylvania announced that a new course for army dentists and surgeons had been established at the Evans Dental Institute, Fortieth and Spruce streets, under the direction of Dr. Charles K. Turner, dean of the dental school.——Thirty-two advanced students, who are not only practicing physicians and surgeons, but who are at present actively engaged as officers of the Medical and Dental Corps of the Army, have been detailed to Philadelphia for the school. The course will continue during the period of the war. While the University Dental School has been designated as the headquarters of the course, some of the branches and laboratory work are being done at the Jefferson Medical College, Jefferson Hospital, Baugh Institute of Anatomy of the Jefferson College, Medico-Chirurgical Hospital, Philadelphia General and the Pennsylvania.——The commissioned officers sent to the school from the United States Dental Corps are: surgeons: Major E. J. Johnson, Capts. R. E. Balch, Carl Eggers, A. P. Roope, R. C. Wiggon; Lieuts. Ivan R. Burket, Bernard Friedlaender, S. D. Gleeton, C. W. Hoffman, R. M. Kleckner, F. Koontz, A. J. McCracken, W. H. Maley, J. W. Means, Samuel Oast, Jr., Howard Schriver and E. M. Vaughan. Dental surgeons: Lieuts. Vincent E. D. Bragg, R. S. Catheron, H. O. Cowles, F. H. Cushman, H. T. Hinrici, W. H. Hynard, C. J. Meyer, G. C. Parry, S. D. Ruggles, W. J. Scruten, I. E. Smith, J. D. Stone, C. W. Swing, C. E. Waters, J. B. Williams and P. J. Wumkes.

CANADA

Officers Wounded.—The following officers of the Canadian Army Medical Corps were recently reported wounded: Lieut.-Col. Anson S. Donaldson, Calgary, Alta.; Capts. James E. Bloomer, Moose Jaw, Sask.; J. Harold Jones, Vancouver, B. C.; Richard W. Kenny, Winnipeg, Manit.; Robert Mackenzie, Vancouver, B. C., and James Moore, Listowel, Ont.

Medicated Wines.—The Ontario License Board is instituting an active campaign against the "medicated wines." According to an amendment to the Patent Medicine Law recently passed at Ottawa, the board can now proceed with prosecutions under the Ontario Temperance Act, which carries a maximum penalty of $1,000 fine. It is understood that the board will proceed direct against the manufacturers and not the druggists.

Notification of Venereal Diseases.—The Board of Health of Toronto, through Dr. Charles J. C. O. Hastings, will ask the Ontario Board of Health to have all persons with venereal disease placed under quarantine, as is the case with all other communicable diseases. They will also seek legislation to provide for any one suspected of being infected undergoing an examination, and, if found diseased, quarantined, the board of health to have the final decision in case of dispute.

Canadian War Cripples.—Douglas C. McMurtrie in *The Survey*, Nov. 3, 1917, gives an account of the work done by the Military Hospitals Commission and allied organizations and officials in Canada for the training of soldiers crippled in the war. This work is now well organized in Canada and decided progress is being made. McMurtrie describes particularly the work in Alberta in the Ogden Military Convalescent Hospital, near Calgary, and also at Edmonton, where well equipped institutions are carrying on this work.

Fee-Splitting in Toronto.—Dr. D. J. Gibbs-Wishart, president of the Academy of Medicine, Toronto, took occasion to rap fee-splitting in his presidential address before that body:

"It is a frankly dishonest transaction which stamps as a fraud the practitioner who demands his pound of flesh." He stated he was credibly informed that men in Toronto had endeavored to solicit the operative work of practitioners on the frankly stated basis of a fifty-fifty division of the fee. He, even—specialist in nose and throat—had been personally solicited by a general practitioner to state what percentage he might expect to receive on referred cases.

Scarcity of Doctors in Canada.—Dr. John W. Edwards, ex-member of parliament, Cataraqui, Ont., says that medical students should be exempted from the military service. Medical officers point out that the public does not realize the scarcity of doctors in Canada at the present time. It is understood that the government intends issuing authority to the exemption boards to allow medical students to continue their studies, in view of the fact that the War Office has sent back to Canada to finish their course second and third-year men of Queen's, Toronto and other medical colleges, who were serving in various capacities overseas.

Cancer in Canada.—Dr. Charles J. C. O. Hasting, M. O. H., Toronto, estimates there are between 7,500 and 8,000 deaths from cancer in Canada every year, and the majority of these, 80 to 90 per cent., are of persons over 40 years of age. Three quarters of those lives might be saved by early diagnosis and proper treatment. He sounds a note of warning to the public and says that as there is no known medical cure for cancer there is therefore no worse criminal than the man who advertises to sell a cure for cancer (or consumption), as he is robbing the victims of their only chance for recovery—early eradication, radium or roentgen-ray treatment.

Hospital News.—Some time ago the Hamilton (Ont.) City Council appropriated $60,000 to $70,000 for remodeling the administration building of the Hamilton City Hospital, but had held back the money. Last week a conference took place between the hospital governors and the board of control, but they failed to come to an agreement as to the absolute necessity of the alterations at the present time.——The Military Hospitals Commission of Canada has decided on the immediate erection of a convalescent home for returned soldiers at London, Ont. Provision will be made for 300 beds, and arrangements will be made later on to expand to a capacity of 600 beds. The Ontario government will bear a substantial proportion of the cost of construction.

Medical Inspection of Schools in Toronto.—The system of medical inspection of schoolchildren now in operation in Toronto provides for inspection in the separate (R. C.) schools as well as the public schools, and for all the year round, instead of for ten months of the year, as formerly. Dr. Marchant B. Whyte, who was superintendent of the Isolation Hospital, has been placed in charge of the work under Dr. Charles J. C. O. Hastings, the former being director of medical services. Under the arrangement the health physicians employed in the schools are required to carry out the duties of medical officers of health, each being assigned a district—the city having been divided into several health districts, five in number, and under this arrangement, likewise, the public school nurses have been incorporated into the general public health nursing system of the city.

Personal.—Capt. John M. Adams, C. A. M. C., who has been overseas for two years, has been recalled to Ottawa for special duty in the department of documents.——Major Andrew Macphail has arrived in Montreal from overseas.——An escaped prisoner from Germany has brought word of the Hon. Dr. Beland, formerly postmaster-general of Canada. He is in good health, but has lived regularly in prison since June last. He is allowed out twice weekly under guard. He gives his medical services freely among the British prisoners and maintains a kitchen at his own expense, and is a very efficient cook. Dr. Beland was not told of the death of his wife until three days thereafter, apparently so that he would not have a good excuse to ask to go to her funeral.——Dr. William H. Hattie, Halifax, N. S., was elected president of the Canadian Public Health Association at its recent meeting.——Dr. Frederick S. Minns, who was acting medical inspector in chief of the board of education in Toronto when it was transferred to the Department of Public Health, has resigned.——Drs. Norman E. McKay, M. O. H., Halifax, N. S., and Napoleon Boucher, M. O. H., Montreal, Que., have been members of a special committee under the food controller, inquiring into the milk supply of Canada.——Capts. Charles A. Temple and William J. Clark and Major W. Harley Smith, Toronto, who have been in England for two years, have returned.——Lieut.-Cols. Irving H. Cameron, Toronto, Clarence L. Starr and John D. Courtnay, Ottawa; Major Donald McGillivray, Toronto, and Dr. Robert B. Wilson, roentgen-ray expert, Montreal, have started from Halifax to make an official visit of inspection of all the military hospitals of Canada from coast to coast.——Capt. H. A. Simkins of the Spadina Military Hospital, Toronto, has been transferred to England.——Dr. J. Gordon Gallie, Toronto, has resumed practice after service abroad.——Capt. Andrew S. Moorhead, Toronto, is now doing surgery in France under Lieut.-Col. Herbert A. Bruce, Toronto.——Capt. Roland W. Young, Oshawa, Whitby Military Hospital, has been transferred to the Toronto Military Base Hospital.——Major Andrew Macphail, Montreal, editor of the *Canadian Medical Association Journal,* has gone to visit his old home in Prince Edward Island.

GENERAL

Correction.—At the Physicians' Club banquet to Dr. Billings, described last week, it was stated that Governor Lowden was introduced by Dr. A. M. Corwin and that Dr. Arthur O'Neil acted as toastmaster. Dr. A. Augustus O'Neil acted as toastmaster and introduced Governor Lowden.

Correction.—In publishing the list of chiefs of the medical service in the cantonment hospitals in The Journal for Oct. 20, 1917, Major William S. Bigelow of Boston was given as the chief of the service of Camp Cody, Deming, N. M. This should be Major Edward B. Bigelow of Worcester, Mass.

Paul Jones Club Officers.—At the annual meeting of the Paul Jones Club, Sons of the American Revolution, held at Portsmouth, N. H., November 7, Dr. Henry I. Durgin, South Eliot, Me., was elected president, and Drs. William O. Junkins, Eugene B. Eastman, Portsmouth, and Fred S. Cowle, Portsmouth, were elected members of the board of managers.

Ohio Valley Physicians Elect Officers.—At the nineteenth annual meeting of the Ohio Valley Medical Association, held in Evansville, November 7, the following officers were elected: president, Dr. J. Rawson Pennington, Chicago; vice presidents, Drs. Walter F. Boggess, Louisville, Ky.; Meyer L. Heidingsfeld, Cincinnati, and Virgil H. Moon, Indianapolis, and secretary-treasurer, Dr. Benjamin L. W. Floyd, Evansville (reelected).

Eye, Ear and Throat Men Meet.—At the twenty-sixth annual meeting of the American Academy of Ophthalmology and Oto-Laryngology, held in Pittsburgh, October 29 and 30, the following officers were elected: president, Major Allen Greenwood, M. R. C., U. S. Army, Boston; vice presidents, Drs. Virginius Dabney, Washington, D. C.; Frank R. Spencer, Boulder, Colo., and W. Likely Simpson, Memphis, Tenn.; secretary, Dr. Lee Masten Francis, Buffalo, and treasurer, Dr. Secord H. Large, Cleveland.

Bequests and Donations.—The following bequests and donations have recently been announced:

University of Pennsylvania, $600,000 from the executors of the will of Eckley B. Coxe; of which $500,000 is to be used for the Unversity Museum, and $100,000 for the pay of professors and keepers.

St. Luke's Hospital, Bethlehem, a gift of a ward, costing $90,000, from the Bethlehem Steel Company, October 18.

The Board of School Commissioners, Indianapolis, his medical laboratory for the use of physicians and others needing information, and the Presbyterian Board of Missions, his instrumental and surgical equipment by the will of Dr. John Kolmer.

St. Bartholomew's Clinic, New York, $10,000; the Morristown (N. J.) Memorial Hospital, $100,000; Germantown Dispensary and Hospital, $100,000; St. John's Guild, New York, $50,000, and Babies Hospital and St. Mary's Free Hospital for Children, New York, each $100,000 by the will of Mrs. Mary Warden Harkness.

St. John's Guild and Hebrew Orphan Asylum, New York, each $500, by the will of Joseph Morningstar.

Augustana College, Rock Island, Ill., his library, by the will of Dr. Carl Oscar Bernhardi, Rock Island.

FOREIGN

De Quervain Succeeds Kocher.—F. de Quervain, now professor of surgery at the University of Basle, has accepted a call to the medical faculty of Berne as successor to Kocher.

Jadassohn Called to Succeed Neisser.—J. Jadassohn, who has been professor of dermatology at the University of Bern since in the nineties, and is said to have been practically the founder of dermatology in Switzerland, has now gone to Breslau to take the chair left vacant by the death of his old teacher, Neisser, some months ago. He was born not far from Breslau, in 1863.

Beretta Prize for Milan Physicians.—Dr. A. Beretta of Milan bequeathed to the city of Milan a fund of $40,000, the income of which is to be awarded as a biennial prize for the best work on clinical medicine or pathologic anatomy done during the two years by some physician who has resided in the province of Milan for at least five years, but has not been in practice longer than twelve years. The money prize is to be accompanied with a gold medal.

Memorial to Gutierrez of Madrid.—A statue of Gutierrez, Count of San Diego, was recently unveiled on the grounds of the Rubio Institute at Madrid, three years after the death of this leader in gynecology in Spain. Among the speakers, Cortezo, president of the Academia de Medicina and editor of the *Siglo Medico*; classed Gutierrez with Letamendi and Cajal as Spain's great modern trio. He remarked further that the fame of the practitioner is ephemeral, even the best beloved, but a monument prolongs it and thus makes up in part for the inadequate compensation which the fees for his visits represent in return for the persevering devotion and self abnegation which the practice of medicine signifies.

Deaths in the Profession Abroad.—**Sir David Caldwell McVail**, Glasgow, Scotland; L.F.P.S. (Glas.), 1866; L.R.C.P. (Edin.), 1866; M. B. University of Glasgow, 1876; aged 72; formerly professor of clinical medicine in St. Mungo's College, Glasgow; physician to the Glasgow Royal Infirmary; Crown member for Scotland of the General Medical Council; a member of the Court of Glasgow University, since 1891; a prolific writer on the mechanism of respiration and diseases of the respiratory organs; died at his home in Glasgow, November 4.——**E. Huet**, one of the pioneers in electrology in France, aged 57. He had charge of the electrotherapeutic department at the Salpêtrière, and the account of his work and honors is practically the history of electrodiagnosis during the last twenty-five years.——Lieut.-Col. **F. E. Viana**, professor of surgery at the Medico-Military School at Mexico City.——**P. Malerba**, research worker and professor of physiologic chemistry at the University of Naples, aged 68.——**D. Sangrador** of Madrid, killed in a railroad accident while on his way to the recent medical congress at Valladolid.——**J. Rambousek**, professor of factory hygiene at the University of Prague, and an authoritative writer on industrial poisonings.

LONDON LETTER

London, Oct. 23, 1917.

The War

MINISTRY OF HEALTH POSTPONED

The prime minister, Mr. Lloyd George, received a deputation from the joint committee of approved societies and the conference of the Amalgamated Society of Industrial Assurance, representing about 12,000,000 insured persons. The objects of the deputation were: 1. The early establishment of a ministry of health on lines satisfactory to national health insurance organizations. 2. The early passage into law of a bill for the simplification of insurance administration. 3. The financial readjustment of national health insurance by a further grant. The premier said that the exchequer was not in a position in the middle of a great war to make the same promises in regard to insurance or any other social projects that it could very well make in days of peace. Our energies and our thoughts had been taken away from projects for the amelioration of the condition of the people to the terrible demands made on us in the defense of our liberties. The drain on our resources was unparalleled, and we were not at the end of the charge on our national wealth. He wished he could predict that we might soon see the end of it, but the task which the nation had taken in hand must be accomplished. Otherwise not merely the power and prestige of this nation were broken, but its future was pretty hopeless. We must husband our resources and incur no obligations beyond the strictest and sternest necessities of the hour, and when demands were put forward for improvements here and there, his answer would be, "Concentrate on victory." For the moment every claim on the exchequer must be considered in the light of the terrible possibilities of the war; and when it was over, in a freer and happier atmosphere we could begin to rebuild, reconstruct and regenerate. As to the bill for a ministry of health, Mr. Lloyd George said he was the last person to contend that it was not an urgent measure. We had to repair the ravages of the war. Stricter attention to the health of the community and to the saving of life by that means was one of the most efficient and surest methods of attaining that end. The damage would be great, even if the war was arrested now. The losses would be beyond count; and we should have to devote resolution, courage and readiness to find an agreement which this war had disclosed rather than seek for a point of controversy—we should have to apply the whole of that new spirit to proposals of this kind. Otherwise we should never repair within our day, nor within the day of our children, the ravages of this great war; but if we did concentrate in that spirit we should not merely clear the débris of war, we should not merely restore, but we should build something stronger, grander and on a firmer foundation than we had ever witnessed. He was certain that in one form or another we must drastically reform the administration of our health laws. There were conditions that were incompatible with health. It was a scandal that a nation which had shown such capacity for meeting great emergencies should have lethargically tolerated conditions of that kind. It was regrettable that people capable of the sort of explosive energy which this country had put forth in two or three years should have allowed slums, misery, and wretchedness and squalor to drain the land. We wanted people who enjoyed liberty to be fit to defend it, and that was one of the problems of the future.

THE MEDICAL TREATMENT OF INVALIDED SOLDIERS

The Army Council has issued revised instructions relating to the continued treatment and training of soldiers discharged from the army on medical grounds. Two categories of patients are contemplated in these instructions: (1) soldiers who at the actual time of their discharge require further treatment, and (2) soldiers who at some time after their discharge are found to require further treatment. This category is confined to men suffering from ailments arising from wounds or injury sustained during military service. As a general rule, the patients to whom these instructions apply will be those suitable for treatment as outpatients in hospitals, because army regulations in force already provide that so long as inpatient treatment is required, soldiers shall not be discharged from hospital. It is foreseen, however, that in certain special cases, as in tuberculosis or paraplegia, further inpatient treatment may be necessary. The further treatment thus to be afforded will be available at military Red Cross hospitals through agency of the local war pensions committees. In order that the local committees may efficiently carry out the duties devolving on them, they are to be furnished with cards, recording all relevant information relating to men about to be invalided out of the army. These cards will indicate whether or not further treatment is needed, and, if so, where it may be obtained. The committees will also be empowered to appoint hospital visitors, to visit and confer with the hospital authorities—or the medical authorities at command depots and camps—responsible for men about to be invalided out. In addition to treatment, special courses of technical training may in many cases be desirable. Patients for treatment in the second of the two categories described above must themselves make application in the first instance to the local committees. After ascertaining the eligibility of the applicant, the committee will send him to a military hospital for examination. The hospital will furnish a card, as described above, giving authority for the further treatment of the applicant.

FOOD ECONOMY

Sir Arthur Yapp, president of the Y. M. C. A., has undertaken the direction of a new food economy campaign, which is necessary in view of the dearth of many of the principal foods. Next month a flood of oratory is to be let loose throughout the country. A committee of experts in the food controller's department is working out a scientifically graded scheme of rationing. Taking into consideration the available supplies of food and the needs of our allies, they are seeking to find out exactly what each man, woman and child ought to have according to age and occupation and other relevant circumstances. As soon as they have reached decisions, the scale of consumption which they recommend will be made known. The rationing will be for all essential foods. It will be our task to see that the scale is observed. In addition it will be necessary to ask people occasionally to make a definite sacrifice and for a time to go without some particular thing altogether. Sir Arthur Yapp is endeavoring to establish a league or committee of national safety to bring home to the people that our national safety and the allied cause generally depend on the extent to which we economize in food consumption. The first members of the league will be asked to do everything possible to educate others. They will be asked to pledge themselves to live within the scale of rations laid down and to avoid waste. It is hoped to evolve a scheme to keep in touch with members so that once a month points for use in the campaign can be sent to them.

THE NATIONAL HEALTH IN 1916

The report for 1916 of Sir Arthur Newsholme, medical officer of the Local Government Board, has just been issued.

A review of the national health of the present time is rendered exceptionally difficult by the disturbances of population due to the war and to the gigantic new industries which have been created. So far as ordinary infectious diseases are concerned, with the exception of measles, the record of 1916 has remained favorable. There have been no cases of cholera. The tuberculosis work of local authorities during the year has been further restricted by the war. One of the most urgent of after-war problems will be to secure the early resumption and extension of this work, particularly in regard to the provision of greatly increased hospital accommodation for persons with advanced cases of consumption. The reduction in the number of births emphasizes the importance of saving child life and of improving the health of all survivors. Sir Arthur Newsholme considers that there is no insuperable difficulty in reducing the total deaths in childhood to half their present number. During 1916 the rate of infant mortality was the lowest on record. Owing to a large proportion of health officers having been released for military service, an increasing number of women physicians have been appointed for public health work, the depletion of the services having become serious. Unless considerable readjustments are made, more officers cannot be spared for the army consistently with the public safety. The staffs of inspectors of nuisances had also been greatly depleted, and many untrained men and women are performing duties formerly in the charge of trained men. It is not surprising that under these conditions, outbreaks of infectious diseases in a few instances have not been promptly controlled, and that, especially in regard to smallpox, enhanced risks have been, and continue to be, incurred owing to the inexperience of the local officers. A large part of the time of those medical inspectors who are not on military duty is taken up in emergency work arising out of the foregoing considerations. Health officers and sanitary inspectors remaining on civil duty have done admirable work in assisting less experienced temporary colleagues in other districts. In a not inconsiderable number of instances, one officer has acted for several areas in addition to his own.

PARIS LETTER

Paris, Oct. 18, 1917.

The War

RESULTS OF ANTITYPHOID AND ANTIPARATYPHOID VACCINATION OF THE SOLDIERS DURING THE WAR

An interesting communication on this subject was read by Prof. H. Vincent at a recent meeting of the Académie des sciences. He said that in the present war, during the winter of 1914-1915, a very severe, rapidly progressing epidemic had made its appearance. Because of the exigencies of war, preventive vaccination could not be made effective at the front during that period. A less serious recurrence of paratyphoid took place during the fall of 1915. Since then the armies at the front have enjoyed an unusually good state of health. Typhoid and paratyphoid have existed only in a very slight degree, in spite of the presence of the aggravating conditions of exceptional severity brought about by a violent and prolonged war; by the mobilization of large numbers of troops, such as have never been observed before in any war; by the constant arrival of new troops; by the close contact of many men, thus increasing the danger of direct and indirect contact through the agency of the sick, as well as by carriers; and by the flies and the continual contamination of the soil.

The wholesale vaccination of the troops at the front was commenced in February, 1915. Since the beginning of the war the laboratory of the army has sent to the front 5,513,073 doses of vaccine. Before the war and since the year 1911, 20,000 soldiers have been vaccinated against typhoid and paratyphoid A and B with mixed or triple vaccine; 200,000 others have been vaccinated against typhoid only. At the present time, thanks to this active immunization, these diseases can be considered as having been practically vanquished. From 6.12 in November, 1914, 7.24 in December, 1914, and 7 in January, 1915, per thousand men, the number of cases dropped rather suddenly to 4.3, 2.49 and 1.6. In August and September, 1915, the morbidity (paratyphoid predominant) rose to 2.47 and 2.65, but since then it has diminished more and more. During February, 1916, the percentage of cases per thousand was less than 1, and this percentage has been maintained. In 1917, the monthly rate was: 0.1, 0.048, 0.025, 0.028, 0.036, 0.064, 0.068 and 0.063 per thousand. As for the mortality, from the fastigium of the 1914-1915 epidemic (November to March), the curve descended almost vertically to the present time. The vaccination by two injections is responsible for this remarkable recession in the number of cases and deaths, and the mortality is now so low that one is obliged to evaluate on the basis of 100,000. Even when we reduce to that scale, the percentage is often fractional. In 1917, it has been successively 0.6, 0.5, 0.5, 0.1, 0.3, 0.6, 0.4 and 0.3 per hundred thousand.

The value of this specific prophylactic measure cannot, in fact, be determined precisely. If the morbidity and mortality of these typhoid diseases as observed from November, 1914, to January, 1915, had been maintained, one could estimate, on the basis of 4 or 5 million soldiers having been sent to the front during the thirty-eight months of the war, that the number of cases of typhoid would have exceeded a million, with 145,000 deaths. This is not taking account of the aggravating influences obtaining during the war and the unusual weather conditions of the fall months of the three years during which this war has been waged; consequently, this preventive vaccination may be credited with having been of immense economic value to the army as well as to France as a whole. Taking for comparison the health of the French army before the war, as set forth in the official statistics for the year 1911 (the last published), it will be seen that at present the number of cases of typhoid fever occurring in the armies at the front are more than seven times less numerous, and that the number of deaths is 8.5 times less numerous than during peace times.

SHELL FRAGMENT IN THE LEFT AURICLE

At a recent session of the Académie de médecine, Dr. Le Fort reported an observation made on a wounded soldier from whose left auricle he extracted a piece of shell the size of a pea. Of the six walls of the left auricle, only one is accessible, the postero-inferior, the narrow space bounded by the pulmonary veins, the auricular appendage and the auriculoventricular vessels. The shell fragment had been fixed with the fingers in a fold of the auricular wall; two loops of thread were passed at the base of the fold. Then the auricle was incised with a bistoury, the fragment extracted and the threads tightened. Complete hemostasis was effected. The patient died on the fourth day. The necropsy showed that the sutures had held perfectly, that there had been no hemorrhage in the pericardium, and no blood clots were found in the heart. The patient was 45 years of age, and he had recovered from a pulmonary affection shortly before he was wounded. The intrapleural space was entirely obliterated. The heart was small and fatty, with fatty perinephritis of the right kidney, slight hydronephrosis of the left, etc. Dr. Le Fort has thus far performed seven operations for the extraction of foreign bodies from the heart, and four pericardial extractions with one death and ten recoveries.

Repression of Public Drunkenness

October 1, a law, dealing with the repression of public drunkenness and the supervision of saloons, was promulgated. This law imposes on persons found in a manifest state of drunkenness on the streets a fine of from 1 to 5 francs for the first offense. The second offense is punishable by from one to three days' imprisonment, and a third offense, when occurring within the first twelve months, is punishable by imprisonment for from six days to one month or a fine of from 16 to 300 francs. Any person who is convicted twice may be deprived of his electoral and civic rights for two years. The law fixes an analogous penalty for such dealers as shall serve liquors to minors (under 18), and dealers who are fined more than once will be liable to closure of their establishments for a year or more. The sale of alcoholic liquors on credit is interdicted. The law forbids the employment of females under 18 years of age in retail liquor establishments, unless they are members of the proprietor's family. Dealers who encourage debauchery shall be imprisoned for from six days to six months, and shall forfeit their political rights for five years. Their establishments shall be closed permanently.

Treatment of War Fractures

At one of the recent sessions of the Société de chirurgie of Paris, Dr. Heitz-Boyer, chief of the surgical clinic of the Faculté de médecine de Paris, described the organization and method of procedure of the Fracture Center at Châlons-sur-Marne, of which he is director. This center was established for the following reasons: (1) to assure patients, whose condition often demands many months of hospital residence, of continued care under conditions which must obtain if the surgeon is to assume full responsibility; (2) to provide that the care is always given in a center of this kind properly equipped from the point of view of the necessary material organization, apparatus and procedure; (3) to institute such care as early as possible, endeavoring to keep in mind the military as well as the surgical needs; (4) to assure the evacuation of these patients at the earliest possible time to the next unit formation within the same surgical group.

From the application of these principles has been born the special surgical "bone group" in each army, consisting of three grades or divisions, comprising the principal formations situated in the rear of the lines where operations are performed. Farther back in the interior are two branches, the first known as the second hospital, where the discharged patients, or those who are out of danger, are hospitalized until such time as the wounds have healed and the bones have united; and a second, known as the division of physiotherapy where the convalescents and those who are to be discharged from the army on account of disability receive such care as will restore to them as much function as their injury permits. Therefore, the treatment of the wounded is always under the surveillance and direction of a single responsible head. All records are carefully kept and interchanged, so that complete observations may be made, and the value of different procedures employed by the single units may be compared. Finally, from a material point of view, each group can be so well equipped that all kinds of work can be done, the equipment sufficing to take care of the wounded in the different stages of their illness. The apparatus accompanies the wounded into the different relays of the entire course. The results obtained by Heitz-Boyer in his center, where he has treated, since April, nearly 700 cases of fracture, more than 100 of these involving the thigh, have been so good that the value of this team-work method is fully attested.

New School for the Reeducation of Disabled Soldiers

The president of the republic recently visited a new school for the vocational reeducation of the mutilated, founded by the Union of Foreign Colonies in France in the Ferme de Champagne at Juvisy-sur-Orge for the benefit of war victims. The new school was founded exclusively for the benefit of mutilated or wounded agriculturists. It includes sections for general training, horticulture, nurseries, agricultural mechanics and automobile traction. Since the opening of the school, 550 patients have been admitted. A large number have been returned to their homes, properly benefited; for the others, lucrative positions have been obtained by the union. The principal workers in establishing these foundations, in which cooperated American, English, Dutch, Norwegian, Russian and other committees, constituting the Union of Foreign Colonies, are: Mm. Ascher, L.-V. Benet, L. Kone and B.-J. Shoninger, vice presidents.

The Bread Card and the Composition of Bread

Commencing October 15, a rigorous bread card régime was instituted. The maximum quantity of bread allowed for the weekly consumption of each individual was fixed on the following basis: for persons from 1 to 6 years of age, 300 gm. per day; more than 6 years of age, 500 gm. In addition, a flour ration of 50 gm. per day is provided for infants under 3 years of age; on the other hand, a supplementary ration, not exceeding 200 gm. per day, is allowed for all persons who shall make satisfactory declaration to the effect that such addition is indispensable to their nourishment. A second supplementary ration, not to exceed 200 gm., is allowed to persons engaged in hard work, and whose food consists largely of bread.

The composition of bread provoked an interesting discussion in a recent session of the Académie de médecine. The following resolutions were adopted: (1) the miller must grind only grain which is sound, free from foreign bodies and altered grains, that is, good and not damaged grain; (2) the percentage of the boltage cannot be uniform; it necessarily must vary with the quality of the grain, as determined by the weight of a hectoliter (2¾ bushels); (3) acting on the directions so far received, it seems that the present regulations in vogue have brought about the distribution of bread which has in a certain number of cases caused some illness; (4) the method of making bread with lime water, besides having many advantages, does not seem to cause any inconvenience from the health standpoint; (5) in regard to substitutes for cereals, it is very desirable to use rice in the French diet as much as is possible. Rice flour, as well as barley, rye, buckwheat and corn flour can be added to wheat flour for bread making. If well prepared, these flours do not give rise to any untoward effects.

Association News

THE CHICAGO SESSION

Local Committee on Arrangements for the Chicago Session of the American Medical Association

The following constitute the Local Committee on Arrangements for the session of the American Medical Association to be held in Chicago, June 10-14, 1918: Drs. Ludvig Hektoen, chairman; Charles J. Whalen, secretary; W. A. Pusey, John V. Fowler, Hugh T. Patrick, M. L. Harris, Charles F. Humiston, J. B. Herrick and Frank Billings.

Marriages

Lieut. Philip Emerson Thomas, Jr., M. R. C., U. S. Army, Camp Beauregard, Alexandria, La., to Miss Louise Walls of Holly Grove, Ark., October 28.

Samuel Lutz Zurmehly, M.D., Rushsylvania, Ohio, to Miss Ethel Long of Kingston, Ohio, at Chillicothe, Ohio, October 26.

Major Arthur Wells Elting, M. R. C., U. S. Army, Albany, N. Y., to Mrs. Francis W. Rawle of Bryn Mawr, Pa., October 25.

Walter Scott Patterson, M.D., Butler, Pa., to Miss Gertrude Connors of Penn Township, at Butler, October 24.

John Thomas Sullivan, M.D., Milwaukee, Wis., to Miss Lona Chapman of North Fond du Lac, Wis., October 27.

August Edward Witzel, M.D., Utica, N. Y., to Miss Helen Marguerite Van Alstyne of Ilion, N. Y., October 24.

Robert Morton Manson, M.D., San Leandro, Calif., to Miss Madeline Strohl of Oakland, Calif., October 31.

John C. Reed, M.D., Duquesne, Pa., to Miss Lillian Bennethum of Harrisburg, Pa., October 24.

Peter Burrell Mulligan, M.D., Hazleton, Pa., to Miss Helen Leonard of Camden, N. J., recently.

Audley Durand Stewart, M.D., Rochester, N. Y., to Miss Jane Walker Russell of Chicago, recently.

Walter Martin Skallerup, M.D., Walker, Iowa, to Miss Belle Forrester Black of Chicago, June 27.

Pattison Albert Waters, M.D., Monte Vista, Colo., to Miss Ethel Keen of Denver, October 7.

Deaths

Newell Bly Burns, M.D., North Wilmington, Mass.; Harvard Medical School, 1909; aged 35; a Fellow of the American Medical Association, and a member of the National Association for the Study and Prevention of Tuberculosis and the American Sanatorium Association; assistant superintendent and physician to the North Reading (Mass.) State Sanatorium for Tuberculosis; instructor in pulmonary diseases in Tuft Medical School, Boston; died in the sanatorium, October 27, from rheumatic endocarditis.

Harris Gray Sherman, M.D., Cleveland; College of Physicians and Surgeons in the City of New York, 1880; aged 61; a Fellow of the American Medical Association, and a member of the American Academy of Ophthalmology and Oto-Laryngology, and American Ophthalmological Society; a specialist on diseases of the eye; first medical inspector of schools of Cleveland; at one time president of the Cleveland Chamber of Commerce; died in Charity Hospital, Cleveland, October 30, from pneumonia.

Francis L. Springer, M.D., Newport, Del.; University of Pennsylvania, Philadelphia, 1877; aged 63; formerly a Fellow of the American Medical Association; a member of the Delaware State Medical Society, and its president in 1912; for nine years trustee of the poor, and once a member of the visiting staff of the State Hospital, Farnhurst; for several terms physician of New Castle County; died suddenly at his home, October 24, from cerebral hemorrhage.

Lieut. George Walter H. Conrad, M. R. C., U. S. Army, Philadelphia; Hahnemann Medical College, Philadelphia, 1913; aged 29; a specialist on diseases of the eye, ear, nose and throat; who had been on duty at Fort Benjamin Harrison, Ind., until August 27, when he was transferred to the aeronautical school at Austin, Texas; died in the Army Base Hospital, San Antonio, Texas, October 30, from abscess of the brain.

John C. Webster, M.D., Lafayette, Ind.; Rush Medical College, 1870; aged 76; a Fellow of the American Medical Association; formerly president of the Indiana State Board of Medical Registration and Examination; consulting physician to St. Elizabeth's Hospital, Lafayette; died, November 11, from the effects of carbolic acid accidentally self-administered, in mistake for liquid petrolatum.

Jefferson A. Davis, M.D., Kansas City, Kan.; Medico-Chirurgical College of Kansas City, Mo., 1902; aged 54; a Fellow of the American Medical Association; for eight years coroner of Wyandotte County, Kan., and formerly police surgeon of Kansas City, Kan.; died in St. Margaret's Hospital, Kansas City, Mo., October 7, from heart disease.

Andrew Jackson Hall, M.D., Natchez, Miss.; Bellevue Hospital Medical College, 1879; aged 78; formerly a Fellow of the American Medical Association; vice president of the Mississippi State Medical Association in 1892; a member of the staff of the Natchez City Hospital since 1889; a Confederate veteran; died in New Orleans, October 21.

Horace Edward Bunce, Jr., M.D., Pittsburgh; Western Pennsylvania Medical College, Pittsburgh, 1900; aged 47; formerly a member of the Medical Society of the State of Pennsylvania; a member of the medical staff of the Jones and Laughlin Mills, Pittsburgh; died at his home, October 28, from septicemia.

George L. Saunders, M.D., Columbus, Ohio; Ohio State University, Columbus, 1908; aged 43; a member of the Ohio State Medical Association; formerly a member of the staff of the Ohio Hospital for Epileptics, Gallipolis; died in Grant Hospital, Columbus, October 29, from disease of the intestine.

John Milton Dexter, M.D., New York City; College of Physicians and Surgeons in the City of New York, 1894; aged 49; formerly a member of the Medical Society of the State of New York; was run over and killed by an automobile, near his home, November 1.

Albert Nathan, M.D., Charleston, S. C.; Medical College of the State of South Carolina, Charleston, 1909; aged 31; a member and once secretary of the South Carolina Medical Association; died in Boston, October 22.

Paul S. Morrison, M.D., Bancroft, Kan.; Ensworth Medical College, St. Joseph, 1909; aged 33; for several years a druggist and physician of South St. Joseph, Mo.; died in a hospital in Atchison, Kan., November 2.

A. C. McNutt, M.D., Bucyrus, Ohio; Starling Medical College, Columbus, Ohio, 1856; aged 89; surgeon of the Eleventh Ohio Volunteer Infantry during the Civil War; died at his home, October 16, from uremia.

Abraham L. Lehman, M.D., Philadelphia; Medico-Chirurgical College of Philadelphia, 1899; aged 62; a pioneer of the Coeur d'Alene district; died in the Providence Hospital, Wallace, Idaho, October 21.

William Albert McCallie, M.D., Knoxville, Tenn.; Vanderbilt University, Nashville, Tenn., 1876; aged 65; formerly a member of the Tennessee State Medical Association; died at his home, October 18.

James H. Dobbins, M.D., Bellefonte, Pa.; University of Pennsylvania, Philadelphia, 1849; aged 90; formerly a member of the Medical Society of the State of Pennsylvania; died at his home, recently.

Dennie Daniel Trotter, M.D., Madison, Ga.; Atlanta, Ga., School of Medicine, 1912; aged 28; formerly a member of the Medical Association of Georgia; died in a hospital in Atlanta, October 16.

Decatur H. Burk, M.D., Warner, Okla.; Medical College of Georgia, Augusta, 1889; aged 67; formerly a member of the Oklahoma State Medical Association; died in Muskogee, Okla., October 24.

John Kolmer, M.D., Indianapolis; Jefferson Medical College, 1894; aged 51; a Fellow of the American Medical Association; a well known surgeon of Indianapolis; died at his home, October 21.

John Craig Johnstone, M.D., Lawton, Okla.; St. Louis University, 1912; aged 34; formerly a member of the Oklahoma State Medical Association; died in Blackwell, Okla., October 7, from diabetes.

James M. Bartholow, M.D., Urbana, Ill.; Rush Medical College, 1871; aged 70; a member of the Illinois State Medical Society; a veteran of the Civil War; died at Champaign, Ill., October 8.

James A. Summers, M.D., Johnson City, Tenn.; College of Physicians and Surgeons, Baltimore, 1874; aged 69; died at his home, August 4, from dysentery and laryngeal tuberculosis.

Rudolph Myers, M.D., Huntingdon, Pa.; Bellevue Hospital Medical School, 1863; aged 77; a Fellow of the American Medical Association; died at his home, August 24, from toxic myocarditis.

Edward Johnson, M.D., Columbus, Neb.; Medical School of Maine, Portland, 1883; president of the First National Bank of Columbus; died in the Clarkson Hospital, Omaha, October 27.

Newton C. Davis, M.D., Kingman, Kan.; Homeopathic Hospital College, Cleveland, 1884; aged 61; formerly a member of the Kansas Medical Society; died at his home, about October 25.

Samuel A. Orentreich, M.D., Denver; University of Krakow, Austria, 1890; died in Detroit, October 23, from the effect of poison, self-administered, it is believed, with suicidal intent.

Robert Lee Ray, M.D., Monterey, Tenn.; University of Tennessee, Nashville, 1892; aged 52; a Fellow of the American Medical Association; died in his office, October 29.

Isaac B. Gallup, M.D., Willimantic, Conn.; Philadelphia University of Medicine and Surgery, 1869; aged 72; died at his home, August 2, from carcinoma of the bladder.

Levi A. Horn, M.D., Austin, Pa.; University of Louisville, Ky., 1894; a member of the Medical Society of the State of Pennsylvania; died at his home, about August 15.

Samuel O. Knapp, M.D., Frankfort, Ind.; Medical College of Ohio, Cincinnati, 1884; aged 59; died in Mulberry, Ind., September 20, from chronic interstitial nephritis.

Charles Z. Ellis, M.D., Berkeley, Calif.; California Eclectic Medical College, Los Angeles, 1891; aged 54; died in Berkeley, October 16, from carcinoma of the stomach.

F. N. Sheppard, M.D., Riverside Manor, Md., American College of Medicine, Philadelphia, 1865; aged 78; died at his home, near Crumpton, Md., October 14.

Andrew N. Falkenstein, M.D., Glen Rock, Pa.; College of Physicians and Surgeons, Baltimore, 1887; aged 63; died at his home, October 19, from nephritis.

Henry T. Fullerton, M.D., Kenton, Tenn.; Missouri Medical College, St. Louis, 1866; aged 77; died at his home, September 4, from cerebral hemorrhage.

Charles C. Dalton, M.D., Wiota, Wis.; Bennett Medical College, Chicago, 1903; aged 39; died in Madison, Wis., September 15, from pneumonia.

Thomas C. Van Tries, M.D., Bellefonte, Pa.; University of Pennsylvania, Philadelphia, 1868; aged 38; died in Pittsburgh, August 1, from pneumonia.

John G. Rogers, M.D., Cherrygrove, Tenn.; Vanderbilt University, Nashville, Tenn., 1875; aged 78; died at his home, July 14, from nephritis.

Merriken B. Lukens, Atlanta, Ga. (license, Georgia); a practitioner since 1871; aged 83; died at the home of his niece in Atlanta, October 22.

John R. Bartlett, Burlison, Tenn. (license, Tennesse, 1889); aged 61; a practitioner since 1880; died at his home, July 28, from angina pectoris.

Joseph George Church, M.D., Shenandoah, Pa.; University of Pennsylvania, Philadelphia, 1887; aged 52; died at his home, October 19.

Jesse B. Mitchell, Sneedville, Tenn. (license, Tennessee, 1889); aged 76; died at his home, August 22, from cerebral hemorrhage.

Joseph James Harrison, M.D., Loudon, Tenn.; University of Nashville, Tenn., 1854; aged 83; died at his home, October 25.

Charles Dingee, M.D., Burlington, N. J.; University of Pennsylvania, Philadelphia, 1887; died at his home, October 10.

Joseph Lewandowski, M.D., Boston, Mass.; University of Krakow, Austria, 1894; aged 53; died at his home, October 23.

Oran A. Dean, M.D., South Haven, Mich.; University of Buffalo, 1868; died at his home, October 19.

The Propaganda for Reform

In This Department Appear Reports of the Council on Pharmacy and Chemistry and of the Association Laboratory, Together with Other Matter Tending to Aid Intelligent Prescribing and to Oppose Medical Fraud on the Public and on the Profession

IODEOL AND IODAGOL

Report of the Council on Pharmacy and Chemistry

Iodeol and Iodagol (formerly called Iodargol) are products of Viel and Company, Rennes, France, widely advertised in this country by David B. Levy, Incorporated, New York. The claim made for both preparations is that they depend on "colloidal iodin" for their action. They are put up in a number of forms, for instance:

"Iodeol Ampoules each containing 1 c.c. (20 centigrammes colloidal iodin in an oily vehicle)."

"Iodeol External, containing 50 per cent. colloidal iodine."

"Iodagol Ampoules, each containing 2 c.c. (50 centigrammes colloidal iodine in an oily vehicle)."

The claim is, that, the iodin being in the colloidal state, it has the properties of elementary iodin and thus the preparations may be used in concentrations and under conditions which would make the use of free iodin impossible. The products have been extensively and extravagantly advertised for use in a wide range of conditions. Thus Iodeol has been proposed in the treatment of:

"Pulmonary Tuberculosis"
"Laryngeal Tuberculosis,"
"Glandular Tuberculosis"
"Tuberculosis of the Bones"
"Pneumonia, Broncho-pneumonia, and Congestive Conditions"
"Whooping Cough, Influenza, Asthma"
"Typhoid Fever"
"Syphilis"
"Obesity".

Iodagol, which is for external use, has been advised in the treatment of:

"Gonorrhea and its Sequelæ"
"Cystitis"
"Tetanus"
"Wounds complicated by gaseous gangrene"
"Burns"
"Old Suppurations, ulcers, abscesses, etc."
"Articular rheumatism"
"Abscess Alveolar"
"Pyorrhea Alveolaris"
"Stomatitis (Canker-Sores)."

Nearly two years ago the American agents requested the Council to consider Iodeol and Iodagol for admission to New and Nonofficial Remedies. The information submitted in regard to their character and composition was vague and indefinite, the pharmacologic information practically nil and the clinical data as voluminous as it was unconvincing.

On the basis of chemical, pharmacologic, bacteriologic and clinical investigation carried out under the direction of the referee and a study of the submitted evidence, the referee reported:

1. Iodeol and Iodagol do not contain the amount of iodin claimed.

2. The iodin is not present as elementary iodin, but instead the preparations behave similarly to the well-known organic iodin compounds such as iodized fats.

3. The therapeutic claims made for the preparations are exaggerated and unwarranted.

In view of his findings he recommended that Iodeol and Iodagol be declared inadmissible to New and Nonofficial Remedies for conflict with Rules 1 and 2 (misleading statements regarding composition and identification) and Rule 6 (unwarranted therapeutic claims). The Council adopted the recommendation of the referee, directing inclusion of the full report in the annual Council reports after submission to the manufacturer, and recommending publication of an abstract of this report in The Journal.

This report was brought to the attention of the American agent, David B. Levy, Inc., and through them to the French manufacturers, E. Viel and Company. The manufacturers have intimated that they will not file a reply to the report. The firm of David B. Levy, Inc., has decided to sever its connection with these products and to discontinue their sale.

W. A. Puckner, Secretary.

Referee's Report

Iodeol and Iodagol were submitted to the Council nearly two years ago as "electro-colloidal iodine" and with the claim that they produced all the antiseptic and other effects of ordinary iodin without any of its side actions. The referee has done much work on the subject, conducted a large amount of correspondence and has contended with long delays. He feels that the consideration of these products should be brought to a conclusion and accordingly he submits this report of their consideration. The following is a summary of the report, which is appended:

I. Discrepancy in Iodin Percentage.—The examination at the Chemical Laboratory of the American Medical Association, as well as that of the referee, shows that the various samples of Iodeol and Iodagol examined contained a little less than one-half of the total iodin claimed. These facts were reported to the American agent. After a lengthy delay a reply was received which presented a double excuse: (1) that the full amount of iodin had been added, whatever had become of it later; (2) that the claims were made for "colloidal iodin" and that this is not elementary iodin in the colloidal state, but a preparation of iodin containing only 50 per cent. of real iodin. Neither explanation can be taken seriously, as they are obvious quibblings. The referee concludes that the preparations are falsely labeled as to iodin content.

II. Nature of the Iodin Compound in Iodeol and Iodagol.—In the information sent the Council, Iodeol and Iodagol were defined as "A suspension of electro-chemical colloidal iodin in a vehicle of purified oil." Numerous inquiries have failed to elicit more specific information from the manufacturer or his agent. The statement of composition can mean only that the preparations contain free iodin (but in colloidal form) suspended in oil. No evidence to substantiate this claim has been submitted. (There is evidence that the preparations contain colloidal particles, but it does not indicate if this colloidal material is iodin, or a combination of iodin or indeed whether the colloid component contains any iodin.) The recent statements of the agent seem to concede that what they call "electro-colloidal iodin" contains only about 50 per cent. of real iodin, in other words that it is not "colloidal iodin" at all but a mixture or combination of iodin with some other unnamed substance. This, of course, is something very different.

Certain results reported from the American Medical Association's Chemical Laboratory suggest that the so-called "colloidal iodin" of Iodeol may be a combination of iodin with a volatile oil. The investigations of the referee indicate that the iodin exists in a rather resistant form or combination behaving altogether differently from ordinary free iodin, and rather resembling the behavior of iodin substitution products, such as iodized fats or phenols. Briefly, then, the recent admissions of the agents indicate that Iodeol does not contain "colloidal iodin" in a chemical sense, and there are indications that it does contain its iodin in a rather firm (chemical) combination.

III. Chemical Properties of Iodeol.—From a study of different specimens of Iodeol, the referee concludes that fresh specimens contain *no free iodin* and that old ones contain small amounts as a result of decomposition. Iodeol has the solubility characteristics of fats and fat-like compounds. The examination, as a whole, shows that Iodeol contains a peculiar and rather resistant form or combination of iodin. There is nothing in the chemical data that suggests that it could act differently from ordinary iodin compounds, such as iodized fats. It would not act as ordinary iodin.

IV. Pharmacologic Data.—The pharmacologic statements which were submitted were loose and apparently meaningless or misleading. In reply to questions submitted by the referee, the manufacturer finally had some work done and submitted a report by Jean Laumonnier. The referee was unable to confirm some of this work, and as a whole it does not appear materially to elucidate the action of Iodeol. From a consideration of the submitted evidence and as a result of his own work, the referee concludes that Iodeol does not behave like elementary iodin; it does not coagulate proteins and therefore is not irritant. It is presumably absorbed, but quite probably after chemical change; it is changed into iodid and, like organic iodids, is excreted somewhat more slowly than when inorganic iodids are administered, but the difference does not appear important.

V. Antiseptic and Bactericidal Action.—Elementary iodin is considered a fairly powerful agent in these respects. The activity is presumably due to changes in the proteins, etc., of the bacteria, analogous to the effects which produce pain, irritation and necrosis of the tissue cells. Since the latter effect is not produced by Iodeol, it seems highly improbable, if not impossible, that it should act on bacteria like elementary iodin. It is entirely unjustifiable to credit the known antibacterial qualities of ordinary iodin to "colloid" iodin. This misrepresentation is especially prominent in the circular "Notable New Therapeutic Agents," as will be seen, for instance, from the following citations:

> "Iodine has long been universally recognized as an antiseptic of extraordinary potency. Not only is it rapid and certain in its germ-destroying action, but it also possesses an attribute denied many other antiseptic agents, namely, the power to penetrate and impregnate the tissues. Other antiseptics, as is well known, act on the surface epithelium only."
>
> "According to Kinnaman (Journal A. M. A., Aug. 26, 1905), iodine is far superior to bichloride of mercury, a two per cent. solution killing streptococcus pyogenes in two minutes. Iodine does not coagulate albumin, and is very penetrating."

The citations imply that this "colloidal iodin" of Iodeol and Iodagol acts as an antiseptic like ordinary iodin, except that it is claimed to be more efficient by "diffusing" more readily. This is entirely unjustified and misleading. If Iodeol and Iodagol are really antiseptic, they must act by some other mechanism than that through which elementary iodin acts, and such antiseptic action would have to be demonstrated by direct observation and not assumed from the known action of free iodin.

Antiseptic and bactericidal effects are easily estimated by laboratory methods. Yet no evidence on this point appeared to have been available until the Council called for this. Laumonnier then carried out some experiments which were in turn submitted to bacteriologic control. The bacteriologist failed to obtain any results with some of the tests, and considered the other data of little value.

The claim that Iodeol and Iodagol have the antiseptic and bactericidal action of free iodin lacks proof and must be considered unwarranted and misleading in the extreme.

VI. Clinical Trials.—The manufacturers and agents of Iodeol presented many letters from physicians; but few, if any, of these gave evidence of careful, critical, controlled observations. They could not, therefore, be considered as acceptable evidence. The more important claims, letters and published papers, however, were submitted to clinical specialists collaborating with the Council, with the request that they examine these and conduct some clinical trials, if they considered it advisable. The results obtained in these preliminary trials did not appear sufficient to warrant further experimentation.

From a consideration of the evidence presented, the referee concludes that the claims made for Iodeol and Iodagol are unwarranted, exaggerated and misleading. He recommends that Iodeol and Iodagol be declared ineligible for New and Nonofficial Remedies for conflict with Rules 1 and 2 (misleading statements as to composition and identification) and with Rule 6 (unwarranted and misleading therapeutic claims). He further recommends that the Council authorize publication of the preceding summary of the consideration of Iodeol and Iodagol in The Journal and inclusion of the full report in the annual Council reports after submission to the manufacturer.

Garbage Saving at Army Cantonments.—Another practical demonstration of what may be done in the use of garbage is made by the War Department in the Army training camps. The garbage of thirteen of the cantonments will be sold to a contractor for feeding swine, yielding the government an annual price of $446,394. It is estimated that garbage waste from ten to fifteen soldiers will feed one hog, putting onto the animal 1 pound of weight per day. At this rate garbage from thirteen cantonments will produce 18,900,000 pounds of pork yearly. In cases where garbage can not be used for feeding, it will be treated for grease extraction and the tankage ground for stock food or fertilizer. The custom of burning garbage will be abolished altogether. The War Department will receive $240,000 annually for the manure from the horses and mules at Army cantonments.—*Weekly Bulletin.*

Correspondence

"DISORDERED ACTION OF THE HEART" IN BRITISH SOLDIERS

To the Editor:—The report on soldiers returned as cases of "disordered action of the heart" of the Medical Research Committee in England has recently been supplemented by reports of the detailed clinical studies made by members of the staff, contained in *Heart,* **6,** No. 4. The most striking features of these excellent and very detailed studies are, first, the negative conclusions as to the etiology and pathology of this syndrome, and, second, the positive conclusion that graduated exercises cure a large proportion of the patients.

These patients show certain symptoms which to my mind are most significant—breathlessness, and blood pressure and pulse reactions to exercise. The authors state that "the response of the respiratory rate to exercise is a very exaggerated one." Again, "None of our patients are capable of such effort (i. e., amounts of work healthy young adults are capable of) : equal distress and similar pulse rates and systolic pressure are produced by smaller amounts of work or work done more slowly. It is clear that if we chose a given amount of work as a stimulus and apply the stimulus to healthy controls and to our patients, the latter react to the stimulus in an exaggerated fashion. The pulse rate rises much higher than in controls, and the high rate is longer sustained, the blood pressure rises higher, and the raised pressure is longer sustained than in controls: the summit of the blood pressure is not delayed,[1] however: breathlessness, fatigue and palpitation are also much more in evidence."

It seems to me very clear that the patients who presented the foregoing symptoms were suffering from a decreased cardiac reserve power. The fact that so many of them were cured by graduated exercises affords additional and convincing proof. The neurotic symytoms that were often present are not necessarily a sequence of the decreased cardiac reserve power, but probably are simply a concomitant. Very possibly they are caused by the same factors that produced the decrease in cardiac reserve power.

We frequently see these patients with decreased cardiac reserve power in civil life, and graduated exercises cure them. One half of the patients described in the report dated the onset of symptoms a number of years back. Infections of various kinds contracted during service immediately preceded the onset of symptoms in another large group. The cardiac reserve power is always lowered after any infection of moderate severity. Any one who has indulged in exercise too soon after a sojourn in bed with fever can appreciate the truth of this statement. The report takes cognizance of this etiologic factor when it states that "convalescent treatment should be more prolonged than is often the case; a graduated system of retraining seems most desirable."

A group of patients is described who suffered from precordial pain and in many instances hyperesthesia of the chest wall, both accentuated by exercise. The circulatory reactions of this group to exercise are not given except in one instance, probably because it was inadvisable to carry out exercise experiments on account of their effect on the pain. These patients are quite rare in civil life, and their subsequent histories would be of much value.

Objections may be made to my use of the term "cardiac reserve power." The heart's total capacity is made up of two component parts; one, the smaller, comprises the power expended in furnishing the requirements of the metabolism with the body at rest; the other, by far the larger, is utilized when physical work is performed. It is this potentially large component that is called into action by graduated exercises. Any expression which describes a definite function of a bodily organ has a perfectly legitimate use. In this instance the term "cardiac reserve power" denotes a most important function of the heart, the variations of which are matters of personal experience to every man who has gone through a course of physical training. Our inability to measure the heart's reserve power directly is not a reason for ignoring its existence.

---

[1] The summit was not delayed because the authors in each experiment stopped increasing the work just as they were about to reach a "delayed rise." The controls were given from ⅓ to 4 times more work than the patients (comparing the maximum amounts given). Had the authors been a little more persistent they would have found the "summit of maximal pressure is delayed" exactly as they found it was in normal patients and with decidedly less work.

When the reserve power is impaired, not from organic disease of the heart, but from any one of numerous causes, there is presented a characteristic clinical picture which to my mind the authors of this report have described quite accurately. The neurotic symptoms from which these patients suffer do not alter the significance of the respiratory and circulatory reactions to work or the significance of the curative effect of graduated exercises.

Theodore B. Barringer, Jr., M.D., New York.

THE CARREL-DAKIN TREATMENT

To the Editor:—I am enclosing a letter which I wrote recently to Dr. William H. Welch in regard to the Carrel method of wound treatment which is at present so actively under discussion. I believe that it presents a point of view that might very well be presented to the profession at this time through the columns of The Journal.

Arthur Dean Bevan, M.D., Chicago.

My Dear Dr. Welch:

I want to write you about a problem which I think is of considerable importance to the Medical Corps at this time and in which I believe you are interested. The problem is that of the Carrel method of wound treatment. I of course have followed in the past two years the surgical literature on this subject with a great deal of interest. At the meeting of the American Surgical Association this spring, Dr. Charles Gibson of New York read a paper on this subject, and at the American Medical Association meeting in June, Dr. William Sherman of Pittsburgh discussed the subject before the surgical section. They both presented the subject in a most enthusiastic way and made very startling claims for the new method. These were so out of keeping with the reports that I have been able to obtain from well qualified surgeons of large experience who had the opportunity of employing it in their military hospital work, and were in such opposition to the generally accepted views of surgical pathology and wound repair, that I have taken the pains to go into the subject pretty fully with an attempt to analyze the facts and arrive at a judicial opinion as to its value.

When I was in Washington during the first two weeks in October, I found that classes of men were being sent to the Carrel Hospital in connection with the Rockefeller Institute in New York for the purpose of taking short courses in the Carrel-Dakin method. On leaving Washington I went to New York and spent one morning at the Carrel Institute and had the opportunity of obtaining a syllabus of the work that is being done in these courses, of seeing their hospital and laboratories, and of witnessing one operation done by Josh Hartwell, not under the supervision of Carrel himself, but of a French army officer who is at the hospital and who has been with Carrel for some time.

I found in discussing personally with several surgeons and from letters and reports which I have had an opportunity of reading from Dr. James Neff, who was in charge of a base hospital of a thousand beds or more for a year on the western front, from a report by Dr. George Crile, from a talk with Dr. James Burry, who has had the treatment tried for a number of months in his accident work in the Illinois Steel Company, from the statements made by Fred Murphy and reports from Joe Blake, and personal communication from Sir Berkeley Moynihan, that they and many surgeons were skeptical as to its practical value. I did not venture, however, to form an opinion of my own until I had the opportunity during the last week of reading Carrel's book and analyzing the problem from this report of his own work. I should like to make clear that the views that I express in this letter are not obtained from any hearsay evidence but from an analysis of Carrel's own views expressed in this book. One of the important parts of modern surgery and one of the things that has made modern surgery possible is that division of the science that is known as surgical pathology. By this I mean a division of pathology that has been specially studied and developed by scientific clinical surgeons. It is only necessary for me to state that the development of modern surgical pathology rests on the work of Lister, of Paget, of Billroth, of such men in this country as Fenger and Senn, and is well presented today by the work done by Lexer and presented in a book which is known as Lexer's "General Surgery." From the time of Lister until now, scientific clinical surgeons have studied the special pathologic problems that were involved in the science and practice of surgery. The problems of wound repair, of infection and the processes by which an organism frees itself from infection, separating the living from the devitalized tissues, the extrusion, digestion and encapsulation of foreign bodies, etc., have been studied with the greatest possible care, and many of these problems worked out as thoroughly both experimentally and clinically as in any field of medical science. Analyzing the Carrel work from the standpoint of what is known of modern scientific surgical pathology, I am forced to the conclusion that his work does not at all meet the requirements essential to a piece of scientific research. I take it for granted that the chemical problems involved have been scientifically handled; but the problems of surgical pathology have been handled in a superficial, incomplete way without the necessary controls, and frankly the conclusion is forced on me that Carrel's part of the work is not scientifically proved and cannot be accepted.

It is evident as one analyzes Carrel's statements that it is a piece of work done by a laboratory man who does not understand the clinical problems involved, who either does not know or ignores many essential facts, and whose conclusions as to the miracle working effects of the Dakin solution in his scheme of treatment have about as little basis in fact as the exaggerated claims that have been made for "ambrine" in the treatment of burns. The trouble is that this problem has not been attacked in the right way. A problem of this kind should be attacked by the joint labor of a number of teams, each one composed of a thoroughly scientific clinical surgeon who is well trained in the science of surgical pathology, in conjunction possibly with such a laboratory worker as Carrel, and with the assistance of competent chemists and bacteriologists. It should be attacked in the most scientific and broadest possible way and with the necessary controls, controls that would enable the investigators to determine, first, the results from the employment of the accepted surgical methods of surgical technic as applied, for instance, to a shell wound of the thigh with compound fracture of the femur, including the earliest possible removal of foreign bodies and of devitalized tissue, the complete excision of the wounds with immediate closure in some cases and with free drainage, moist dressing with sterile water in others, the immobilization of the limb and the best possible general care of the patient, and the results of such wound treatment which could be designated as the control compared with similar cases treated with the employment of various antiseptic solutions, including the Dakin fluid. These experiments to be of value would have to be on a considerable scale. I am personally so thoroughly convinced that wound healing and the freeing of tissues and an organism from infection depends so largely on the life processes in the living cells at the point of injury and infection and the reaction of the sum total of living cells that make up the entire individual, and that the important thing that a surgeon can do is to eliminate noxious influences and place the particular part injured and the entire individual in a condition where this wound repair and elimination of infection can go on uninterfered with as little as possible, that I can see but a limited value in the local employment of antiseptics of any kind on the surface of the infected wound. That any antiseptic has any healing property, that any antiseptic is miracle working in the handling of wounds, is inconceivable.

Looking at the problem in a broad way, if we could express in figures the value of the means at our disposal of treatment of the shell and rifle wounds of this war, certainly much more than 90 per cent. of the sum total of the value of wound treatment would consist of the proper employment of the well known and generally accepted rules of surgical technic. Granted that the remaining 5 or 10 per cent. depended on the proper employment of antiseptic solutions, one may be very sure that the choice of one of a half dozen thoroughly tried out antiseptics, such as boric acid, aluminum acetate, Dakin solution, dichloramin-T, hydrogen peroxid, phenol and iodin, would not make any enormous difference in the sum total of the end-results.

If the above statements are true, it would be a serious mistake for the government medical services to adopt the Carrel treatment as a great and wonder-working improvement in our surgical technic, and to force a complicated, possible augmented content of the toxic substance by the chance use at the same time of several products containing small amounts. Recent analyses by Arbenz[1] which have become available in this country give the following statistics, in terms of oxalic acid per kilogram of air dry spice or ready-to-eat vegetable, respectively: black tea 14.3, cocoa 4.8, pepper 4.5, rhubarb 3.2, spinach 2.9, sorrel 2.7, dry figs 1.2, roasted coffee 0.8, roasted chicory 0.7, raspberries 0.5, beans 0.45, potatoes 0.4, beets 0.3, currants 0.3, pears 0.2, bilberries 0.2, oranges 0.1, asparagus 0.09, cherries (with seeds), tomatoes and wine grapes 0.08, rutabagas 0.07, cauliflower 0.06, onions 0.05, Brussels sprouts 0.04, endive and melons 0.03, mushrooms, peaches, flour, lemons, celery, plums and apples, a trace; corn meal, rice and chestnuts, none. An added value of these figures lies in the fact that since oxalates in the urine are in part derived from the dietary oxalic acid which is resistant to oxidation in the body, in cases of oxaluria, physicians are accustomed to prohibit those foods which contain most oxalic acid and which are eaten in sufficient abundance to make the total amount thus ingested worth considering. Ordinarily the proscribed dietary articles include tea, coffee, cocoa, spinach, rhubarb, sorrel, pepper, beetroot and beans.[2] It should be borne in mind, however, that not all of the excreted oxalate is necessarily associated with a food source. Some of it may have a microbiotic origin in the alimentary tract; and its possible genesis through imperfect metabolism of certain organic acids is still debated.

THE THYMUS AND RICKETS

It is practically useless to turn to the textbooks for helpful information regarding the functions of the thymus. At best one will find a series of unverified conjectures, debated assumptions, or a frank statement of our ignorance of the real purpose of this organ. The natural association of the thymus with early life has led to the conjecture that the gland plays a part in growth; for it becomes smaller and smaller as the rate of growth declines. The latest though by no means the final evidence indicates that former statements implicating a retardation of growth after removal of the thymus cannot be substantiated by experiment. Halnan and Marshall,[3] for example, found that extirpation of the gland from young animals had no effect on their growth, even when the testes were removed simultaneously. Furthermore, in observations on castrated animals they could find no evidence of any compensatory mechanism between the testes and the thymus. In recent years another possibility of decided practical importance has been given some attention through the assertions of continental investigators.[4] They have reported changes after experimental thymusectomy that correspond somewhat closely to those observed in rickets; and thus the question of the relation of the thymus to bony growth and its pathologic manifestations is again brought into prominence.. In an investigation conducted at the Physiology Department of Glasgow University under the new national health insurance medical research scheme, Renton and Robertson[5] have come to a seemingly convincing conclusion in this matter. They have removed the whole thymus successfully in a series of animals which survived long enough to permit adequate observations on their growth in comparison with suitable control animals. Renton and Robertson conclude that thymusectomy of itself does not appear to cause any symptoms. Spontaneous rickets in subjects not operated on gives rise to essentially the same symptoms as the European writers have attributed to removal of the organ; that is, thymusectomy does not make young animals more susceptible to spontaneous rickets, and if they develop it, they do so at the same time and in the same manner as control subjects. The British investigators sum up their findings by the decision that removal of the thymus cannot be held responsible for the onset of rickets or similar bony changes. The alleged pathologic manifestations that have been credited to loss of the thymus have in reality presumably been due to the development of spontaneous rickets in young animals. Thus another promise of discovering a function for this organ has been shattered.

THE RELATIVE VALUE OF FRUIT JUICES

Fruit juices are rapidly finding their way into the daily life of the American people. A few years ago they were limited to the delicacies of the home or to syrups of the soda fountains. Today orange juice and grape juice in particular have found a widespread and growing popularity as agreeable beverages. It is scarcely an exaggeration to say, as does one of the large manufacturing companies in advertising its product, that grape juice has become the national drink. The temperance wave that has swept over this country, taken in conjunction with a vigorous and highly effective advertising campaign on the part of various producers, has helped to secure favor for a refreshing and wholesome beverage. The shortage of sugar at present and the prospect of a necessary restriction in the output of syrups and similar "essentials" of the "soft-drink" industry are likely to increase still further the use of palatable fruit juices. In addition to organic acids which lend a tart flavor to them, these beverages, provided directly by nature, contain a considerable portion of sugars which lend a food value to the product. Thus a glassful of grape juice measuring 7 ounces (210 c.c.) will furnish about 200 calories in the form of sugar; and orange juice is about half as rich in food value. Recently the juice of the loganberry has begun to claim recognition in this category. Analyses[6] made at the Oregon State Agricultural College at Corvallis indicate that this fluid likewise contains from 6 to 8 per cent. of sugar in the acid juice. This lends to it a fuel value of approximately 300 calories to the liter, presumably in the form of available carbohydrates.

HOOKWORM IN THE MINES OF CHINA

The danger of hookworm infection in mines is well known. Hookworm disease is prevalent in many of the mines of California, China, France, Hungary, Sicily, South America and Spain. Germany, it is said, has spent over $2,500,000 in direct outlay to control hookworm infection in a few of its mines. The disease has been brought under reasonable control in the mines of Belgium and Wales. The investigations of the International Health Board of the Rockefeller Foundation have brought to light a rather unexpected source of perennial reinfection of mines that applies to China in a way scarcely realized in the other countries mentioned. As stated recently in The Journal,[1] the hookworm problem in China presents unique features because of the widespread employment of human excrement as a fertilizer. The disease is thus easily spread into the agricultural districts. It happens that more than a hundred thousand miners, largely recruited from farmers who have worked barefoot in the moist, larva-infected soil, are employed in the mines of Hunan Province alone. The cooperation of the International Health Board has been solicited to provide measures for the control of a difficult situation brought about by this unusual combination of circumstances.

HEAT LOSS AND WATER ECONOMY IN THE BODY

In 1614, Sanctorius wrote, "He only who knows how much and when the body does more or less insensibly perspire will be able to discern when or what is to be added or taken away either for the recovery or preservation of health."[2] Yet the story of this factor of insensible perspiration, the amount of water lost from the body in vaporization, has been most inadequately written. The part played by water in the body is ordinarily overlooked by the clinician except so far as it is expressed in the volume of the urine or in the genesis of an edematous condition. The water which acts as a solvent for the body's waste may thus, perchance, be taken into consideration; but of the water lost from the organism through the respiratory passage and the skin and its rôle in the dissipation of heat from the body, little is known and less is mentioned. The pathway for the loss of heat naturally varies with the temperature of the surrounding air. At a low temperature there is little evaporation of water. Heat is lost in other ways. At an environmental temperature as high as that of the body or exceeding it, there can be no loss of heat by conduction and radiation, so that water evaporation must remove the whole of it. The study of a large number of persons in respiration calorimeters, in this country in particular, has furnished data for estimating some of the factors just referred to.[3] Under an average environmental condition with medium humidity, normal men from 20 to 50 years old excrete on an average 29 gm. (1 ounce) of water an hour — about 700 gm. a day — through the skin and the air passages. In this manner approximately one quarter of the total heat produced is eliminated. Few normal men exhibit variations of more than one-tenth from this figure. According to Soderstrom and Du Bois,[3] the output of water as insensible perspiration is very little affected in disease. When the heat production is increased, the body responds and dissipates the usual percentage of calories in the vaporization of water. When it is necessary to get rid of unusual amounts of heat, the percentage lost in vaporization is increased. Edema seems to have no effect on the water output through the skin; and cardiac and nephritic patients on the whole give figures close to the normal. Just as there is little realization of the extent of the "invisible" water output, so there is too often a failure to appreciate and a tendency to neglect the water content of the intake in the form of seemingly solid food. An illustrative instance has been cited by Soderstrom and Du Bois in the following meal, which might well be given to a nephritic patient: a small dish of farina, a boiled potato, a portion of tomato and lettuce salad, a small dish of junket, and an apple. This ration contains something more than 23 ounces (690 gm.) of water, a quantity sufficient to carry away the heat that leaves in "insensible perspiration" in the ordinary person.

[3] The literature is reviewed by Soderstrom, G. F., and Du Bois, E. F.: Clinical Calorimetry, Twenty-Fifth Paper, The Water Elimination Through Skin and Respiratory Passages in Health and Disease, Arch. Int. Med., May, 1917, p. 931, from which some of the facts quoted are taken.

Health of Food Handlers.—During the examination of the food handlers of New York City, made through the cooperation of the health department and the American Museum of Safety, which included the examination of 44,042 individuals examined at the Occupational Clinic and 33,000 by private physicians, Dr. Louis I. Harris and Mr. Dublin of the Metropolitan Life Insurance Company made an intensive examination of 1,748 food handlers considered typical of the entire number. These included waiters, waitresses, cooks, male and female, other kitchen employees and bakers. In the entire group there were ten cases of active tuberculosis, twelve of suspected and three of arrested tuberculosis. Forty-one persons gave evidence of active or suspected syphilis, of which thirty-seven were among waiters. This group furnished forty-six persons with flatfeet and an equal number with varicose veins. Among the 211 waitresses examined, 65.8 per cent. showed anemia; 62 per cent. had varicose veins, and 17.1 per cent. were reported as suffering from some form of menstrual disorder. Four waitresses were found to have syphilis. The predominating defect among cooks was organic heart disease, there being thirty-two who showed cardiac disease. Of the cooks, 161 had marked disturbance of the digestive functions. Among bakers no tuberculosis or active syphilis was found, but there were thirty-eight cases of chronic bronchial conditions; thirty had organic heart disease and thirty-three, anemia. The study is valuable as demonstrating the importance of the examination of food handlers both from the standpoint of protection of the health of the community and for the opportunity it offers for the study of occupational groups. Another point brought out in the course of this study is the lack of uniformity of standards and methods of classification used by the various workers in the field of industrial hygiene.

Medical Mobilization and the War

MEDICAL OFFICERS IN ACTIVE SERVICE

At the present time there are approximately 12,500 medical men in active service. This includes Medical Corps officers (a little less than 550), medical officers of the National Guard Army, and officers of the Medical Reserve Corps. Up to date approximately 17,900 physicians have been recommended for commission in the Medical Reserve Corps.

AMERICAN WOMEN'S WAR HOSPITALS UNIT

The American Women's Hospitals, of which Dr. Rosalie Slaughter Morton is chairman, was organized by the War Service Committee of the Medical Women's National Association of the United States. Women physicians to the number of 1,200 have registered with the committee, for home and foreign service. Already a number of physicians have been sent abroad to work under the authority of the American National Red Cross with which the American Women's Hospitals works in close cooperation.

MEDICAL OFFICERS' TRAINING CAMP AT FORT BENJAMIN HARRISON TO BE DISCONTINUED

The Medical Officers' Training Camp at Fort Benjamin Harrison is being discontinued and the medical officers transferred from the training camp to other stations. Those who have not yet completed their instruction go to Fort Riley and to Camp Greenleaf at Fort Oglethorpe. Orders have been issued from the Surgeon-General's Office, assigning Colonel Ashburn and several of the other instructors to the Surgeon-General's Office and distributing the remaining instructors among the other training camps. The ambulance and field hospital units undergoing training at the training camp are now testing their ability for sustained marching. Ambulance Companies Nos. 15 and 17, with one field hospital unit and headquarters, all of which are motorized, were ordered to start on November 9 on a seven-day hike to Georgia. Company No. 17 and the headquarters unit will go to Camp Greenleaf, while the other unit will go to Camp Oglethorpe. At the same time, two ambulance companies and two field hospitals, the sixth and fourteenth in each case, provided with mule motive power, received similar instructions.

SALVAGING CLOTHES FROM BATTLEFIELDS AND CAMPS

The English War Office has set up at Dewsbury a department for the purpose of repairing, restoring and utilizing old uniforms and fabrics recovered from the army and navy. All discarded clothing and fabrics of every sort from the battlefields and camps and from the navy are collected, put into bags and shipped to Dewsbury, where the material is sorted into that which can be cleaned, repaired and made usable, and that which must be discarded as rags and put through processes by which it can be made useful as new material. As many as ninety truckloads of this material have been received at this station in a single day. About 350 women are employed as sorters, who pick out the garments that are in condition to be repaired and used again. All articles capable of being restored are sent to a local firm of dyers and cleaners, by whom they are cleaned. Then they are repaired and reissued to the troops or for the use of German prisoners of war. With a high standard of efficiency and a large turnover, the cost for each article, including large repairs, amounts to about 28 cents. In this way, it is said in the report regarding this matter from U. S. Vice Consul Hamilton C. Claiborne, Bradford (*Commerce Reports*, November 5) that $300,000 worth of uniforms have been salved up to the present. In ten months, a total value of material received and disposed of at Dewsbury was over $3,000,000, and the net profit shown on such material at all the stations amounts to a very large sum. Details are given in the report of the amount of material received, the various channels in which it is disposed of, and the uses to which it is put.

CALIFORNIA'S VENEREAL DISEASE PROGRAM

Last summer there was held in San Francisco a conference on prevention of venereal diseases in California, in the interest of soldiers, sailors, and civilians. The program then outlined has been embodied in regulations recently by the state board of health.

The regulations for the prevention of syphilis and gonorrhea require those in attendance on a case of either of these diseases, or a suspected case, to report the case immediately to the local health officer, who in turn will report it to the state board of health. Such reports are to be made by patient's office number or initial only, but the number or initial used must refer definitely to the physician's record of the case. Physicians are expected to furnish, when reporting such cases, any available data that may be useful regarding the sources of infection and must teach the patient how to prevent the spread of the disease, its seriousness, the necessity for prolonged treatment, and must furnish the patient with approved literature on the subject.

Every city, county, and other health officer is directed to use every available means to ascertain the existence of syphilis and gonorrhea within his jurisdiction. He is required to investigate immediately all reported or suspected cases of syphilis in the infective stage, and of gonorrhea, and may inspect, examine, isolate, and disinfect persons, places and things. He is directed to make examinations of persons reasonably suspected of having syphilis in the infective stage or gonorrhea All prostitutes are to be regarded as coming within the suspected class, but the health officer is forbidden from issuing to such women certificates of freedom from venereal disease. The health officer may require the submission of specimens from cases or suspected cases of syphilis or gonorrhea, for the purpose of examination at a state or municipal laboratory, and it is the duty of the attending physician to furnish such specimens when called on to do so.

Local health officers are directed to isolate reasonably suspected persons whenever isolation is necessary to protect the public health. In establishing isolation the health officer must define the limits of the area within which the isolated person and his immediate attendant shall remain. Isolation is not to be terminated until the patient has become noninfective, unless permission is given by the state board of health or the secretary of that board. Cases of gonococcus infection are to be regarded as infective until at least two successive smears taken not less than forty-eight hours apart fail to show gonococci. Cases of syphilis are to be regarded as infective until all lesions of the skin and mucous membrane are completely healed.

Health officers are directed to use every proper means of repressing prostitution, and are to report to the Bureau of Venereal Diseases any unusual prevalence of syphilis or gonorrhea and any unusual local conditions tending to favor the spread of these diseases.

CLINICS AND HOSPITALS

In preparing a list of approved venereal disease clinics and hospitals, the state board of health is aiming to raise the standards of some of the existing dispensaries and hospitals, to encourage the formation of additional public dispensaries where needed, and to assist persons needing institutional treatment to ascertain which institutions have adequate staffs, equipment and standards. Minimum standards are prescribed for dispensaries and for hospitals.

A dispensary, to be approved for the treatment of syphilis, must treat patients suffering from that disease in a separate department or in the department of dermatology, but there is no analogous restriction with respect to dispensaries for the treatment of gonorrhea. In either case, however, the dispensary must be open at least three times a week, day or evening, and the staff must be adequate both in number and in training. Rooms must be well arranged, and every dispensary must have at its disposal beds for isolation and treatment. Laboratory facilities and equipment, with instruments and apparatus, must be provided. In cases of syphilis, microscopic examinations of the suspected initial lesions must be made; Wassermann tests must be performed in the dispensary laboratory or other approved laboratory, and suitable tests and observations shall be made of all patients for a period of not less than two years after the conclusion of adequate treatment. Salvarsan or an accepted equivalent must be administered to all patients suffering from syphilis, unless there are contraindications.

In an approved dispensary for gonorrhea, systematic examination must be made of the discharges, and facilities for urethroscopic and cystoscopic examinations must be provided and be regularly employed by the attending clinicians. Patients must not be discharged as cured until after repeated negative clinical and microscopic examinations. Adequate facilities must be provided for asepsis and antisepsis.

In dispensaries of both kinds adequate records must be kept and an annual report must be made. The clinicians in attendance must themselves devote the amount of time necessary for intelligently informing new patients of the seriousness of their diseases, the necessity for treatment until cured, and the precautions to be taken to prevent the spread of the infection to others, and in addition the dispensary must furnish approved literature on the subjects. A dispensary will not be approved unless a social service department is maintained and adequate measures adopted to procure the regular attendance of patients. If it becomes necessary for any reason to discharge a patient still uncured, the patient must be referred to an approved clinic or to a reputable physician

In general the standards for hospitals for syphilis and gonorrhea are similar to those for dispensaries, but it is specifically provided that patients having venereal diseases must be accepted under the same conditions as other patients.

NEWS OF THE TRAINING CAMPS

At Fort Oglethorpe

Lieutenant McDonald of the Signal Corps has been detailed by the War Department to make a series of moving pictures of the work being done at Camp Greenleaf toward training civilian doctors for military work. If there are any physicians left in this country who imagine that all they have to do in order to serve in the Medical Corps is to change their civilian clothes for a uniform and begin "pushing pills" to the sick soldier, please advise them to see these pictures if they are ever exhibited in their communities. Let them see the workings of an ambulance company, field hospital, regimental or sanitary unit, and then wonder whether they could take charge and run one as smoothly as the trained man. Surprising as it may be to them, doctors are in charge of these outfits, have to run them, and are responsible for all properties connected with them, as well as the training of the enlisted personnel. Moreover, these doctors were untrained civilian surgeons or physicians four months ago.

Majors Van Wart and Owensby have been making a mental survey of the camp for the past three weeks.

Major L. Owen has been relieved from duty at Camp Greenleaf and assigned to the Surgeon-General's Office. The camp has suffered a distinct loss, for Major Owen was one of our most popular and efficient instructors.

Lieutenant-Colonel Talbott, M. C., has been assigned to Greenleaf as camp inspector. Colonel Talbott has had many years' experience in this line of work, and from the amount of interest he has inspired in the student body, we feel safe in predicting "more laurels for his crown."

Major William Pepper, M. R. C., formerly dean of the Medical Department of the University of Pennsylvania, has been made adjutant.

Major Alexander Abbott, M. R. C., has been placed in charge of the school of hygiene recently established at the camp.

Major Walter Weisser has been assigned as provisional director of field hospitals.

Major Bell, formerly connected with the Royal Army Corps, has given a series of lectures on his work in France. Major Bell's ability as a speaker and his unusual opportunities for observing the medical work done in France made his lectures the most interesting in the course.

The Camp Greenleaf Military Society was organized last Friday night. Col. Henry Page, M. C., the commandant, was elected honorary president, and Major Alexander Abbott, president. The aims, objects, etc., of this society are worthy of a more lengthy notice than can be given in this letter—so more about it another time.

Everything is being made ready for taking over the work of the M. O. T. C. at Forts Riley and Benjamin Harrison. The buildings of the R. O. T. C. will be turned over on November 27, which will give accommodations for an additional 5,000 men.

Lieutenant-Colonel Carswell has been relieved from duty with the field hospitals and ordered to San Antonio, Texas. Before leaving, Colonel Carswell was presented with a beautiful wrist-watch by the officers in his command, as a token of their appreciation of his untiring efforts in making the field hospitals one of the best outfits in the country.

Major M. Ashford, M. C., is convalescent from an attack of the grip, and has resumed command of the ambulance companies.

At Fort Benjamin Harrison

CLOSING OF THE CAMP

What is left of the members of the medical officers' training camp at this post will continue their training at Fort Oglethorpe, Ga., as the date for closing the camp here is at hand. The thousands of medical officers who have gone through the training at Fort Benjamin Harrison since the first of June are scattered far and wide. Most of them are still in this country, assigned to base hospitals, field hospitals and regiments. Not a few are in France or at embarkation points.

It is gratifying to the pride of the medical profession for the War Department to admit that the medical branch of the service is prepared to the highest point of efficiency of all. True, it was not necessary to teach us the most obvious part of our work—that of medicine and surgery—as none could receive commissions without first undergoing examination or furnishing evidence of a thorough medical education. However, it has been necessary to begin at the bottom in the education along military lines. Very few had any knowledge whatever of the military side of the life which it bids fair to believe will be theirs for three or four years. This they had to learn, and it has been accomplished in a remarkably short space of time.

GAS DEFENSE

The last of the military lessons, and perhaps one of the most interesting that has been introduced, is that latest flower of Kultur, the gas squad, the Legion of Frightfulness, its insignia a skunk with tail rampant, bar sinister, and the motto "Ad Nauseam."

Insignia of the Legion of Frightfulness.

Three instructors, a trio of frightfulness, descended as a gas cyclone from Fort Sill, Okla. With them arrived an assignment of the gas masks adopted by the United States Army for protection against the poisonous and other gases being used in the present war.

Poison gas was first used in modern warfare, April 22, 1915, by the Germans against a sector of fresh Canadian and French forces, with the double purpose of destroying the morale of the fresh contingents and causing casualties. This was followed by a fresh trial, defensive, against the French attack on the 26th, which was likewise successful. Its use soon became general. This was cloud gas, and as its efficacy depended definitely on atmospheric conditions, gas shells soon were substituted, and now constitute 30 per cent. of the shells used.

The objects in the use of gas are: (1) putting men out of action (casualties); (2) hampering men in artillery, delaying maneuvers; (3) preventing supports and supplies from being brought up, and (4) inspiring general terror.

The gas is used in the form of cloud gas and gas shells in the following varieties:

1. Lacrimatory—direct primary effect on the eyes.
2. Asphyxiating—direct corrosive and irritating action on the respiratory tree.
3. Paralysant—causing central nerve paralysis.
4. Miscellaneous—nauseating and blistering compounds.
5. Accidental—nitrous fumes and carbon monoxid from explosion of mines and high explosives.
6. Mixed.

To combat gas attacks, gas masks and warning are employed. The masks are box respirators of a regulation type. They consist of a canister containing layers of cotton, filters, charcoal, a neutralizing agent—soda lime—and an expiratory shutter valve. Masks are provided with mouthpieces, nose-clip and goggles, fastened into rubber tissue, to protect against tear gases. Warnings come from various sources—aeroplanes and outposts, the whistling sound of the gas itself, which can be heard for 200 yards, smell, the appearance of a cloud of any color, and the loss of the taste of tobacco.

As there is short time allowed to don the mask when in action, drills to speed up its adjustment must be given.

GAS DRILL

There are three preliminary commands: 1. "Mask at carry." Here the satchel is swung over the left hip, with the sling passing over the right shoulder. 2. "Gas alert." The satchel is advanced to the front of the body, with both arms through the sling, and flap open. 3. "Gas" by numbers (adjustment of mask): 1. The right hand is thrust into the satchel and the mask seized firmly, the tube fitting into the palm of the hand, with the fingers grasping the eye-piece. 2. The mask is brought smartly from the satchel, with the fingers grasping the edge of the face-piece, and is brought close to the chin, which is thrust forward. 3. The mask is brought upward, the chin dug into it, and at the same time the elastic bands are placed over the back of the head. 4. The metal breathing tube is seized in the right hand, and the rubber mouth-piece is placed in the mouth. 5. The nose-clip is attached well down over the nostrils. (This is necessary to prevent nose-breathing, as all of the air taken into the lungs must come through the canister containing the antidotes.)

This drill is continued to a point of efficiency whereby it is possible to adjust the masks from "Masks at carry" to the finishing touch of fastening on the nose-clip, in six seconds.

For the purpose of this drill the innocent Docs are ruthlessly lined up, preparedly gassed by lectures, and then forced to don their masks. One look, and there is a mad rush for cameras, to perpetuate their first appearance in the gas masks. That night 300 letters go home, telling of the marvelous experiences and hair-breadth escapes from the gas clouds—shell gas and lecture gas.

As a lesson in anatomy, the gas drill is excellent, and many learn for the first time, while adjusting the nose-clip, the exact position of their noses. The masks also demonstrate that drooling is not exclusively an attribute of infancy, and that bibs may be used to advantage even by medical officers. The constant irritation to the mouth of the tight-fitting mouth-piece fastened to the end of the breathing tube causes an excessive flow of saliva, which escapes through a drip tube out on the chest. It is not an uncommon experience at the beginning of this work, and until one is accustomed to the mouth-piece, for the flow of saliva to be so great as to soak through the clothing.

The first sensation of uneasiness over, and the novelty past, all found to their surprise that the mask, although grotesque in appearance and somewhat clumsy, could be worn without discomfort, and that it permitted perfect freedom in breathing.

This course of instruction, patterned after the British organization, occupies a week, divided between lectures, drills and demonstrations with actual gases at the gas house. It is intended to cover the subject thoroughly and to show the method of protection against poison gases, describe and demonstrate the kind of gases used, and, in the Medical Corps, to give information regarding the symptoms and treatment of those unfortunate victims of this terrible phase of modern warfare.

News Notes from Fort Riley

Preparations for winter are now in progress. Barracks are being banked with earth or supplied with frame or stone underpinning. Stoves have been installed in all barracks and mess halls. Following the blizzards and cold snap of last week, we have had nearly a week of ideal Indian summer weather. Warm, mild sunshiny days and cool, pleasant nights make ideal weather for field maneuvers and bivouacs.

The remnants of Companies 5, 6, 7, 8 and 9 have been consolidated into one company and transferred to No. 6 barracks. This combination is known locally as the "scrambled eggs company," although its own members prefer the title of "Rainbow Company."

No. 7 Mess Hall has been converted into an officers' reading room and library. It is furnished with stoves, tables and chairs, and forms an ideal place for study, reading and letter writing. Medical journals, popular magazines and books are plentifully supplied. This room is generally patronized, and fills a long felt want in the camp.

On Thursday and Friday of last week, companies were taken in a practice march and bivouac to Hay Camp Springs, each man carrying his full equipment with the exception of his bedding roll. The boys supplemented the regulation field reserve ration with rabbit stew, thus furnishing a practical illustration of living on the country.

Field tactics in the morning and regimental maneuvers in the afternoon have given Companies 8 and 9 abundant practice in equitation, on some days giving an opportunity for six or seven hours a day on horseback. Each student officer, in turn, acts as a regimental surgeon, brigade and division surgeon, and is required to issue his orders and carry out his plans. Instruction and practice in locating regimental aid stations, ambulance dressing stations and field hospitals have been greatly enjoyed, the terrain of the Fort Riley reservation affording unusual opportunities for such work.

Major K. W. Kinnard, M. C., U. S. Army, has been ordered to the medical officers' training camp from Camp Sherman, Chillicothe, Ohio, to act as director of field hospitals.

Major George G. Davis, M. R. C., of Chicago, has been relieved as director of field hospitals and assigned to the command of Evacuation Hospital No. 1.

BIVOUAC PRACTICE

One of the things much looked forward to by those men who really enjoy outdoors is the practice march and bivouac. The company, each man equipped with his shelter half, rope and pins, haversack and canteen and carrying the standard reserve ration, is marched out to Hay Camp Springs, which is a delightful place for a bivouac. The pup tents are pitched on each side of the company street, and then the tents, as well as the officers' personal belongings, are carefully inspected by the officer in charge of the party. To accustom the officers to the use of the Lyster bag, no water is permitted to be used until it has been properly chlorinated in the bags, although the water at the springs is of the best. The reserve ration alone is permitted, and no extra food or delicacy of any kind may be taken. Each officer cooks for himself; and the bacon, crisply fried in the meat can, never tastes better than when on such an expedition. The bread comes in two packages, and is in the form of a cracker. Without butter these crackers would be unpalatable indeed; but after being dipped into hot water (heated in the cup going with the canteen) and then mixed thoroughly with the melted bacon fat, they form quite a savory dish. Coffee is made, and completes the menu. While bacon, hardtack and coffee with sugar but without milk may sound to the uninitiated an insufficient meal, it is far from being such. The caloric value is amply sufficient for a heavy man doing heavy work.

To make oneself comfortable in a pup tent requires, first, that one be thoroughly tired, and second, that one be not too badly coddled by the refinements of civilization. The average officer sleeps well, albeit, if the night is cold, it may be an effort to keep warm. Blessed is he whose tentmate does not snore; for with two men in a space as small as that encompassed by a shelter tent, the relation of one to the other is much like that of a pair of spoons in a case. For breakfast, more reserve ration, for luncheon ditto. Cleaning the dishes is not an extensive process, but one that would put the average housewife to her wit's end. Yet with some time and much rubbing, it can be done and done satisfactorily too.

The allowance of equipment taken on the wagons is 50 pounds, which includes absolutely everything. To make sure no one "hunches," the rolls are weighed.

Company 8 in its bivouac had a rabbit hunt. Forming a circle, they managed to scare up and kill some score or so of rabbits, which were promptly transformed into savory stew. The next day's march home finds each officer with a new idea as to just what a bivouac means and how it feels to be on the reserve ration.

NEWS OF THE CANTONMENTS

Twenty-Eighth Division, Camp Hancock, Augusta, Ga.

Representatives from the Surgeon-General's Office recently visited the camp to inquire into the shortage of equipment.

Major Dillinger recently returned from a short leave of absence. He is assistant division surgeon. He has been active in Pittsburgh politics, and was recently a candidate for councilman.

A course of intensive training for the medical officers was begun here, November 1. Among the lecturers are Lieutenant-Colonels Keller and Crookston, Majors Frescoln, Heffelbower, Crampton, Schaeffer, Dillinger, Swayne, Hogan and Schwartz, Captain Stone and Lieutenants Wood, Smith, Laws, Snyder, Seeley, Hollister and others. The course will include the modern advances in military surgery, trench sanitation, French and antigas warfare.

Thirty-First Division, Camp Wheeler, Macon, Ga.

BASE HOSPITAL NOTES

There are at present under treatment in the hospital 1,322 patients, although three wards are still incomplete. Three fourths of the patients have measles, and unless there is an abatement of the epidemic, it will be necessary to occupy the hospital tents pitched for use in case of need. Six tents, each with a capacity of twenty-five patients, are in place, and will be used for convalescent measles patients only should the emergency arise. Heretofore it has been possible to care for all patients under roofs, though all porches and the machine shop have been utilized to that end.

Notwithstanding the crowded condition of the wards, the patients are content, and there are few complaints. When these are made they are at once investigated thoroughly, and relief given as indicated.

The mortality rate speaks for itself, and shows conclusively that even under great difficulties sick and wounded men can be handled satisfactorily. As sequelae there have been nineteen cases of pneumonia, with two deaths.

It should be gratifying to the profession to know that practically every one, from the commanding officer to the lowest private, has risen to the occasion of this emergency; but it is no more than is to be expected. Conditions arise in war which must be overcome, and they are overcome.

The enlisted personnel has been increased by eighty men arriving from Camp Lee. It is believed that there are now enough.

The nurses' quarters are nearing completion, and will be ready for occupancy in a few days, as will the isolation and neuropsychiatric wards. It will probably be necessary to use the latter two for measles patients for the time being.

The mess officer and kitchen personnel are accomplishing the almost impossible task of feeding 1,700 people with a mess hall and equipment intended for 500.

PERSONAL

Captain Pratt has begun his course of instruction in gas defense, which is extremely interesting.

Major Harrold, M. C., acted as one of the judges in the athletic competition at the Georgia state fair.

The Georgia branch of the Daughters of the American Revolution intends to present an ambulance to the Thirty-First Division, for service in France.

Major Pearce Bailey, chief of the neurologic division of the medical service, visited that division last week.

Captain Mitchel, Sanitary Corps, is now on duty with the division as sanitary engineer.

ONE HUNDRED AND SIXTH SANITARY TRAIN

Recently a short problem was workeed out west of the Marion road, 2 miles north of the base hospital site. The tag-patients were detailed from the Florida and Alabama field hospital companies. Work of the regimental detachment was carried out by the hospital corps detachment of the One Hundred and Twenty-Second Infantry, commanded by Major Lindrome. The dressing station was established and the wounded evacuated to the ambulance company dressing station from the regimental collecting point by Ambulance Company No. 121, Capt. Robert F. Ashworth commanding. From the dressing station the wounded were evacuated by the motor ambulances to a theoretical field hospital established at Section 19. Considerable improvement was noted in development of coordinated effort over the problem of last week.

The ambulances of Ambulance Company 124 (mule-drawn) are in process of receiving their initial coat of olive-drab paint, showing in striking contrast to the familiar dark painted bodies.

Additional details of thirty-five men were made for special duty at the base hospital the past week in order to meet the increased demands of the heavy work incumbent on the base hospital. Though further depleting the enlisted personnel available for routine drill and instruction purpose within the train, it is evident that the training received in the actual care of the sick will be of great value in the future work of the train.

Major Cornelius F. Holton, commanding Field Hospital 123 (Georgia), by direction of the division surgeon has pitched the complete ward-tent equipment on the base hospital grounds for use should the emergency require.

Lieut. Daniel P. Campbell has returned from his short leave of absence a happy benedict. Mrs. Campbell has taken up her residence in Macon.

It is with deep regret that we note our first casualty in the train in the death of Private Aubrey Moore of Ambulance Company No. 123, a young man of sterling quality, with great promise of soldierly development. In attending the sick in one of our detailed detachments at the base hospital, he contracted lobar pneumonia. Even as on the field of battle, "he died in line of duty."

The sick rate of the sanitary train reflects credit on the officers and men of the train, being the lowest of any organization in the division.

Again the hopes of the train commander, Major Keenan of Massachusetts, have been raised in the anticipation of the carrying out of the promise of a dinner of "possum and 'taters." As reported two weeks ago, the prospective dinner was stolen from his cage. However, Friday morning a fine fat subject of the possum tribe arrived from some unknown source, and at the present writing we are sure, at least, that said possum is deceased and ready for the oven. Massachusetts still has hope of being convinced that this famous dinner combination is what is claimed for it.

The weekly social of the officers and ladies of the train, with their guests, was held as usual in the recreation hall. The Florida field hospital orchestra furnished the music for dancing. The usual buffet luncheon was served.

The completion of the framing of the tents for cool weather has insured more comfortable quarters. The acquisition of considerable more clothing now renders comparative comfort, especially at night.

Major Job C. Patterson, director of field hospitals, visited last Sunday at the neighboring settlement of Columbus. We have no definite information, but we suspect that a young man's thoughts may turn "lightly to love" even though spring is several months away.

Thirty-Fourth Division, Camp Cody, Deming, N. M.

Enlisted men of the division already present number about 23,000. During the past two weeks the number has been rapidly increasing. The camp is a collection of human beings of wonderfully good quality, and life in it induces a daily growing respect for the man power of America. These men, from our middle western plains, are a bulwark of defense on which the nation may confidently rely.

The spirit of the camp is excellent. It is well expressed in an address delivered by Brigadier-General Mauldin in command of the division on the occasion of the opening of the School for Medical Officers. He said:

> We face an enemy capable and determined, and the task before us will require the best that each man in our Army has in him. But the Army has already accomplished things that seemed impossible. In this war the Medical Department faces the greatest demand that has ever yet been made on the medical profession. The response has been good. Men have made great sacrifices in order to serve the nation, and these sacrifices are appreciated. Our medical officers are ready to work all the time with all their capacity. More than that is required. We must work together. Cooperation with each other and with the rest of the Army is essential if we are to meet the new and unconsidered duties by which we shall be confronted in the war, and win. But we know that each man will give his utmost effort to the United States, and that he will coordinate his efforts with those made by his fellows. We know that each man will be filled with the determination to win, and we shall win.

During the week ending October 22, 2,555 men were examined by each of the medical boards. Of these there were rejected on account of disease by the tuberculosis board (2,342 examined), 10; by the cardiovascular board, 9; by the ophthalmologists, 12; by the board examining the mentally defective, 5. The results of the work of the tuberculosis board are of interest in that they indicate the probable percentage of incidence of pulmonary tuberculosis among the supposedly healthy members of the communities in our north middle states. Cases discovered by this board are incipient. The advanced ones have already been thrown out by the physicians who examined the men on enlistment. This percentage has been 0.5 per cent., and it is probable that during the autumn months this percentage of individuals in any of these communities is developing active pulmonary tuberculosis. Special effort is made to detect these early cases. Organization commanders are requested to send for examination all men in their command who have cough and expectoration, or who show lassitude and inability to perform full duty. New cases are promptly discovered, and the probability of recovery of those thus early detected is great.

VENEREAL DISEASE

The number of cases of venereal disease contracted in or about the camp is gratifyingly small. Since the division came to Camp Cody, Aug. 25, 1917, only eleven new cases of gonorrhea and one case of chancroid have developed. When it is considered that the total number of men in the camp is over 22,000, this affords a gratifying evidence of the efficiency of the measures of prevention that have been instituted. This is a percentage of 0.0036 per month. Many of these patients had not taken the required prophylaxis. They thus come under the operation of G. O. 31, 1912. They are deprived of pay while off duty, and they will be tried by court martial for neglect of duty and failure to obey orders. In contrast with this small percentage of cases contracted here, it is very interesting to note that 440 cases were imported. The anxiety that has been expressed concerning the dangerous moral environment of our troops in camps would be better directed toward the home environment, since the number of cases contracted at home is to the number of cases contracted at camp as 38:1.

The treatment of these cases is a matter of great importance in the Army, since there depends on it the effectiveness of many U. S. soldiers. That which is required in this camp is stated in the following memorandum:

MEMORANDUM ALL SURGEONS, THIRTY-FOURTH DIVISION

The division surgeon desires that the following recommendations be followed as closely as equipment will permit in the treatment of venereal diseases at regimental infirmaries:

GONORRHEA

1. Patients must be instructed in personal cleanliness. They will be advised to wash their hands after each urination and will be cautioned against the danger of infection being carried to the eyes by unclean hands.

2. It is necessary in the thorough treatment of gonorrhea that the penis be cleansed before each injection, with a nonirritating soap and water. Frequently the foreskin is not retracted and the penis is not thoroughly cleansed. The practice of sealing the urethra by means of a small pledget of cotton, which is held in place by retracting the foreskin over the head of the penis, should be avoided. This tends to prevent drainage, and reinfection frequently takes place. The best method of protecting the clothing is to put a piece of clean cotton over the end of the penis to extend about one-third way back and which can be held in place by means of a rubber band.

3. After the above cleansing process, the patient will be advised to urinate before each injection. As gonorrhea is an acute infection of the mucosa of the urethra only, it is necessary that whatever treatment is carried out be nonirritating and one that will not increase the inflammation. When too strong injections are given, posterior urethritis is frequent, and injury to the mucosa occurs which results in chronic gonorrhea or gleet. It is advisable to begin with an injection that is not stronger than one fourth of 1 per cent. protargol. This can be increased, depending on the patients' tolerance and the amount of discharge. Injections should be given every two to six hours by the surgeon, or under his supervision. Care should be taken that the syringe does not traumatize the mucosa and thus open up new avenues of infection. The urethra should not be overdistended, but should be comfortably filled so that the patient has no difficulty in holding the drug at least ten minutes.

The surgeon must insist that all patients drink a large quantity of water, which can be made bland by the use of small doses of sodium bicarbonate. Hexamethylenamin and other urinary antiseptics are very useful, but must not be used in large enough doses to produce irritation of the sphincter and posterior urethra. The injection of large quantities of water causes the urethra to be continually flushed from within out, which is the desired effect. Erections at night should be avoided. Advise your patients to sleep with a little less than the usual amount of covering. It is not desirable that they be chilly or cold, but too much warmth frequently induces erections. When necessary, bromids or other nerve sedatives should be used to control erections.

4. Glass syringes are frequently broken when boiled. They can be disinfected and the gonococcus killed by immersion in a phenol (carbolic acid) solution. Care should be taken that they are thoroughly washed before being used.

5. Much better results can be obtained when using silver salts if the surgeon will have the solution freshly prepared.

6. Frequent examination of the urethral discharge is necessary. This can be accomplished by referring the patient to the base hospital with a note asking that a smear be made. The proper time to obtain such a specimen is before the morning urination.

7. Gleet or chronic gonorrhea is the result of infection into the submucosa of the urethra. It is necessary in this group of cases, after the gonococcus has disappeared, to sound the patient regularly. This will be done by the chief of the genito-urinary clinic at the base hospital, and such patients can be directed to see this officer at the Friday conference and at such other times as the officer may direct.

8. Chronic cases that do not respond to the usual treatment as carried out at the infirmary should be referred to the officer in charge of the genito-urinary clinic, base hospital, for diagnosis and suggestions relative to treatment.

9. Patients requiring endoscopic or cystoscopic examinations will be referred to the base hospital.

CHANCROID

1. All suspicious sores will be referred to the base hospital for diagnosis before treatment is begun. Dressings and medicines of all kinds should not be used before the officer in charge of the laboratory has had an opportunity to obtain some serum for dark field examination. Chancroid is best treated by soaking the penis in some mild antiseptic solution which should be comfortably hot. A saturated solution of argyrol, or the pure crystals of argyrol, applied to such a lesion will usually bring about quick recovery. The inguinal adenitis can usually be controlled by applications of blue ointment. Vaccines are of some use in very chronic cases. The surgeon must be on the lookout for a double infection, as frequently a lesion begins as a chancroid, and later a syphilitic infection develops. When suppuration of the inguinal glands occurs, patients should be immediately referred to the base hospital for treatment.

CHANCRE

1. As mentioned above, every suspicious sore should be examined by the officer in charge of the laboratory, base hospital, so that if syphilis is present, treatment can be started at once. It is necessary to have sterile distilled water for intravenous treatment. Patients requiring salvarsan or neosalvarsan or the intramuscular injection of mercury will be referred to the base hospital. These patients need not remain in the hospital, and can be returned to duty the same day. The Wassermann test is not positive in early syphilis, so that it should not be depended on for a diagnosis. The test should be used in every suspicious case except the early primary lesion. In these cases, as mentioned above, the serum examination for spirochetes is positive in every case of syphilis. A negative Wassermann test does not mean that syphilis is absent. It is necessary that the surgeon study the case together with the laboratory findings before making his diagnosis. Provocative medication is frequently necessary. Mercury can best be used by the inunction method. When this method is used, it is necessary that the surgeon personally supervise the rubbing so that he knows at all times the amount of mercury the patient is absorbing. A good plan to follow is that the men be required to sleep in their undershirts and that the mercury be rubbed into the torso. They should bathe but once a week, at which time the undershirts can be changed. Five treatments per week are sufficient. A course of treatment should take six hours, and consist of thirty rubs.

2. Cases that should be referred to the base hospital: acute epididymitis; posterior urethritis; prostatitis; seminal vesiculitis; suppurating buboes that require drainage; cases for intravenous medication; cases for Wassermann test; in addition, the above mentioned cases for diagnosis and special treatment.

A copy of this memorandum will be posted in a conspicuous place in the room in which venereal treatment is given.

By order of Lieutenant-Colonel.

Some other lines of sanitary work in progress are important. Food is being carefully inspected. All that comes into camp must conform to certain standards. Meat passes the local inspector of the BAI before delivery to the quartermaster, and between the quartermaster and the companies it must pass that of the camp inspector. Milk must measure up to the standards set by the BAI. It must not score less than 75 per cent., and dairies are inspected once in thirty days. Bacteriologic examinations of milk are made, and those dairies whose produce fails to be approved are denied permission to sell to the camp, nor are ice cream factories, bakeries, etc., using this milk permitted to sell to the camp. Canned goods are inspected before issued. Those cans that are leaky and those showing the presence of gas are rejected. The laboratory at the base hospital is now equipped to conduct these examinations for the camp.

The examination of all those concerned in the preparation or handling of food to discover carriers of typhoid or paratyphoid has resulted in the detection of one paratyphoid carrier, who was promptly relieved from duty in the kitchen.

Incoming troops are examined on the train for contagious disease. At the end of their long trips, those trains pull into our sidings, and our newcomers are given a welcome by the band; but before they come within hearing of the martial music, Major Kenney, M. C. N. G., and his staff are already inspecting them, and some unfortunates go from the train directly to the contagious wards of the base hospital. All the others must go to the detention camp of the depot brigade, where during two weeks they carry on in isolation the work of training, before they are admitted into full membership and good standing in our healthy community. Everywhere throughout the camp cases of contagious disease that appear are promptly removed to the hospital, and the contacts, that is, those living in the same tent or in immediate association with them, go to the contact camp out in the unmitigated desert, there to enjoy a noninterrupted view of the far away mountains during whatever leisure is permitted them by the system of intensive training which makes its presence felt even there. The contact camp was commanded by a line officer, there being about 300 men in it; but as this arrangement proved unsatisfactory it is now in charge of Ambulance Company No. 134, commanded by Lieut. F. H. Roost. The Medical Department has taken it over entirely.

Thirty-Fifth Division, Camp Doniphan, Fort Sill, Okla.

A quadrilateral, the monotony of its low and once whitewashed stone walls broken only by the regularly spaced chinks through which one time blazed the fire of the trooper's rifle—such is old Fort Sill.

WORK OF THE DIVISION SURGEON

The sanitary and medical care of the camp is in charge of Lieut.-Col. W. T. Davidson of the Regular Army, under whose efficient and experienced leadership the camp has fared exceptionally well so far. He is ably assisted in this work by Major Carl Philipps, M. R. C., sanitary inspector, and Capt. W. L. Gist, M. R. C., adjutant. One of the difficult problems that the division surgeon had to solve was represented in the water supply. Owing to an unprecedented inadequate rainfall, which has continued now for a period of almost eighteen months, the impounded waters of Medicine Lake, which supply the camp, had become exceedingly offensive from an overgrowth of algae. This condition has now been quite satisfactorily overcome by adequate methods of treatment, to which the present cold weather has given considerable assistance.

The immunization of the troops against typhoid, paratyphoid and smallpox has practically been completed. In addition to these preventive measures, all cooks and those who handle or prepare food are being subjected to special examination to determine their freedom from typhoid germs. So far no carriers have been found.

A special course of instruction in matters pertaining to camp hygiene and sanitation, as well as the special features in the examination of recruits, has been arranged for and is well attended and appreciated. Special examining boards for tuberculosis, cardiovascular, and nervous and mental diseases are also active in weeding out the unfit.

The venereal disease problem also, here as elsewhere, forms one of the important considerations. Since October 1 there have been 322 venereal disease patients under treatment in this division; this makes approximately 1.3 per cent., a figure not excessive when compared with civil life statistics, especially when one considers that under the draft many men already infected are brought into camp.

The general disease incidence for the camp has been low thus far, reaching not quite 2 per cent. Contagious diseases have been relatively infrequent. Since the establishing of the camp in August there have been all told but two cases of cerebrospinal meningitis, nine of diphtheria and fourteen of pneumonia in the division. A case of anthrax with recovery may be mentioned among the more unusual infections that have come under observation. An outbreak of measles in one of the companies was promptly controlled by rigid isolation, and no new cases have been noted.

It is the opinion generally here among medical men that the absence of alcohol has added greatly to the efficiency of the men and to a lessened morbidity.

BASE HOSPITAL NOTES

Pending completion of the base hospital, the sick are being taken care of at the post hospital of Fort Sill. The opening of a number of wards of the new base hospital has made the care of the patients less difficult, however. When all of the buildings are completed there will be hospital accommodations for more than 1,200 patients, a little more than 3 per cent. of the total command. Past experience of the Army Medical Department has shown that this is about the average of sick in large commands.

Major P. B. Connolly of the Regular Army is in command at the base hospital, and the chief branches of the service under him are in the hands of the following Medical Reserve Corps officers: Major A. W. Barksdale, surgery; Major S. Strauss, medicine; Major A. C. Magruder, eye, ear, nose and throat, and Major G. C. Ruhland, laboratories.

Eighty-Third Division, Camp Sherman, Chillicothe, Ohio

Camp Sherman is situated on a broad plain of alluvial deposit on the west bank of the Scioto River. It is 2 miles north-northwest of Chillicothe, which is 50 miles south of Columbus and 98 miles northeast of Cincinnati.

The cantonment is rectangular, half a mile wide and about 2 miles long, and lies in a bend of the river, which for 15 or 20 miles follows a serpentine course. It is in one of these curves that the camp is placed. The barracks and officers' quarters are completed, and most of them are heated.

DISEASE INCIDENCE

There have been about forty cases of pneumonia, but no epidemic. In the second increment of the draft a patient with acute tonsillitis arrived, and before isolation was effective there were thirteen cases; the next day there were eighteen cases and on the third day eleven cases; from then on the epidemic subsided to nine cases, then three, and after the sixth day no other cases appeared. The rapid development of these cases and the prompt subsidence of the epidemic prove the infectious nature of the process and warrant immediate and vigorous action when such cases appear in groups of men. There were eight cases of Vincent's angina, but they yielded promptly to local treatment. One case of epidemic meningitis showed the immediate effects of the injection of Flexner's serum, 400 c.c. of which were injected, partly by the intravenous and partly by the intraspinal route. All contacts were isolated and throat cultures were negative. In the city of Chillicothe there have been sixteen cases of smallpox, but none in the camp. Every draft or enlisted man before his physical examination is completed is vaccinated. The inoculations against typhoid and paratyphoid A and B have been followed by the usual reactions, but there were none of unusual severity.

PERSONAL

First Lieutenant Brainard from the Infantry School of Arms, Fort Sill, Okla., is in charge of the instruction in methods of gas defense and the treatment of gas casualties.

The Ross County Academy of Medicine, October 10, gave a delightful entertainment for the medical officers of the camp. It was well attended, and the president, Dr. F. T. Marr, made a cordial address of welcome which was responded to by Lieut.-Col. Wallace De Witt, the division surgeon. The county societies and the local medical societies as well as the druggists have arranged a plan of cooperation for the improvement of the sanitary conditions of the city and county which should prove of the greatest value and yield excellent results.

The campaign for the Second Liberty Loan obtained the total subscription of over $2,000,000 from the division.

The medical and sanitary problems are in the care of the division surgeon, Lieut.-Col. Wallace De Witt, M. C., U. S. Army, who has been four years at Fort Ethan Allen, Vt., and for two summers in charge of the training camps at Plattsburg, N. Y. Major John A. Burket, M. C., is in charge of the sanitation. Capt. Robert H. Halsey, M. R. C., is assistant division surgeon.

The base hospital, with a capacity of 1,000 beds, is under the command of Major Edward G. Huber, M. C. Major Christian R. Holmes of Cincinnati is chief of the otolaryngologic service. Major Casey A. Wood, M. R. C., of Chicago is chief of the ophthalmologic section. Major James A. Harvey, M. R. C., is chief of the surgical service. Major Dudley DeV. Roberts, M. R. C., is chief of the medical service. Captain Stanley M. Rinehart, M. R. C., is special examiner in tuberculosis. Capts. Henry L. Stick, M. R. C., Elmore E. Adel, M. R. C., and Charles W. Hoyt, M. R. C., are among those doing special work.

First Lieut. Benjamin H. Sherrard, Dental Corps, is directing the work of the dentists, of whom there are about forty-five in the cantonment.

The sanitary train is under the direction of Major Henry S. Satterlee, M. R. C. Major John R. McDowell, M. R. C., commands the ambulance companies. The field hospitals are well organized and almost completely equipped.

That the general health of the camp is excellent is shown by the noneffective rate, which is 14 per thousand.

Eighty-Sixth Division, Camp Custer, Battle Creek, Mich.

Preparations are being made through all regimental sanitary detachments to systematize the work of examining the remaining draft increment that is due to arrive almost any day. This will represent 55 per cent. of the original draft. With the experience gained through the examinations of those already here, there is no doubt that the large number expected will be run through with rapidity and precision. It is expected that there will be fewer discharges on account of physical disability than among the first examined, owing to the fact that the examining boards in the draft districts will be more thoroughly trained through the experience they have already had. The division surgeon has outlined plans which, when carried out, should make it possible for every medical officer to gain some experience in this form of examination and some practical knowledge of the paper work necessary in making out reports for acceptance and for discharge. Changes which are contemplated following an outlined course of instructions as suggested by Colonel Munson, U. S. M. C., will cause a general mix-up of all medical officers for the purpose of instructing them in the necessary detailed work of every medical organization in the division. Field hospital and ambulance company officers and enlisted men will be changed to regimental detachments, regimental detachment officers and enlisted men to field hospitals and ambulance companies, thus making it possible for every medical officer to become familiar with the work of the various organizations, making for greater efficiency in every department. Courses of lectures by line officers and experts in military hygiene, sanitation and the various medical and surgical specialties will be given and must be attended by all medical officers. This is not done with the view of making specialists of medical officers, yet it is very necessary that the medical personnel be thoroughly trained in all branches represented by these courses of instruction.

The Calhoun Medical Society of Battle Creek met Tuesday evening, November 6. Major Roy Bishop Canfield read a paper entitled "Consideration of Some Types of Sepsis and Their Results." Major Ernest Edward Irons read a paper entitled "Chronic Muscular and Articular Rheumatism: Treatment as Based on Etiology." These papers were discussed both by the civilian physicians and the members of the Medical Department, who were present in large numbers.

SANITARY TRAIN

The weather conditions have improved so that outdoor work has been progressing rapidly. Long hikes with maneuvers are daily occurrences. The men relish the change, as lecture work and indoor drills were becoming very tiresome.

Ambulance Company No. 340 gave a large banquet to the officers of the company Tuesday evening, November 6. Invited guests were Major E. C. Jackson, director of ambulance companies; Major Lewis Wine Bremerman, director of field hospitals, and Capt. C. J. MacGuire of Ambulance Company No. 337. Home talent was utilized, and a very enjoyable evening was the result.

Athletes are numerous in the sanitary train. The ambulance companies have developed an extraordinarily fine football team. They have been coached by Capt. H. H. Varner, commanding Ambulance Company No. 340, late coach of the University of Virginia. The team has been unbeaten this season, and has challenged any football team from any sanitary train in training at the present time.

BASE HOSPITAL

The base hospital is nearing completion, and in a short time will be in a position to carry out all its work in a normal manner. Major Wood, commanding, is to be congratulated on the manner of conducting the work there to date, handicapped as he has been by cramped quarters, inclement weather, incomplete heating arrangements, and other difficulties. All patients have been given fine care, and there has been no complaint from any quarter.

Eighty-Ninth Division, Camp Funston, Fort Riley, Kan.

This camp was originally planned for one infantry division and one depot brigade. Now, however, there are really three divisions: the eighty-ninth, white; the ninety-second, colored, and the depot brigade, while the division surgeon's office, therefore, is practically handling the work of an army corps. Nevertheless, the work of examining the men of the National Army has been done quickly and smoothly. It has been so systematized that one examining board has frequently examined over a thousand men in a day, including the administering of smallpox vaccine and the initial dose of the typhoid and paratyphoid prophylaxis.

A training officer, Medical Department, has been appointed for the Eighty-Ninth Division, and a schedule of instruction for the officers and men of the Medical Department has been instituted. Special subjects pertaining to work of the line are given in nightly lyceum lectures, by special officers of the departments concerned. The medical subjects necessary for the instruction of the enlisted personnel are taught by medical officers of the various organizations to which these men belong.

Col. Frank W. Weed, M. C., is sanitary inspector of the Eighty-Ninth Division. Major J. M. White, M. R. C., of St. Paul, is sanitary inspector of the Ninety-Second Division. Capt. R. B. Irones, M. R. C., of San Diego, Calif., is instructor in gas defense for the Eighty-Ninth Division.

The base hospital of Camp Funston is located at Fort Riley, 4 miles away. Patients, and clothing to be fumigated, are taken there and returned by ambulances over the new government macadamized road. A simple system of paper work has been instituted for these transfers, and no confusion results. At present, out of the whole command, there are approximately 30 cases of measles, 25 cases of cerebrospinal meningitis, 35 of mumps, 2 of scarlet fever and 50 of lobar pneumonia. No serious accidents have occurred, the worst being the loss of three fingers by a private who was fashioning a wooden rifle with an ax.

VENEREAL DISEASE

In civil life we have all heard of the great frequency of venereal diseases among soldiers of the Regular Army. In view of this teaching, it may be of interest to note our experiences in the examination of the National Army men just out of civil life on their arrival in camp. For the white troops the incidence of all venereal diseases has ranged between 5 and 6 per cent.; for the colored troops, over 20 per cent. These are all cases contracted prior to enlistment. At the time of present writing, no case has been reported that has been contracted since entering the military service in the Eighty-Ninth Division, which should furnish food for thought.

TYPHOID VACCINATION

A number of officers and men had received their typhoid prophylaxis prior to the order which made paratyphoid vaccination likewise compulsory. These men have subsequently had to take the three doses of paratyphoid A and B vaccine, whereas the men of the National Army have received only the three doses of U. S. triple vaccine, which consists of the paratyphoid and typhoid vaccines combined. It has been an experience common to the medical men of the camp that the reaction from the inoculation of paratyphoid vaccine, alone, has been much more severe than that of the triple vaccine or of the typhoid vaccine, alone. So far, no explanation has been attempted.

"SOB LETTERS"

An unpleasant phase of a medical officer's life is the "sob letters." Dozens of these, in tenor all alike, came through here every week. Anxious mothers, overzealous wives, and even mere acquaintances flood us with affidavits and letters about the physical condition of some of the men brought here by the draft. Some of these letters are extremely sad, others are absurdly funny, but all alike are given full consideration, which means a reexamination of the person referred to, by the already overworked surgeon. These letters rarely amount to anything, as the men unfit for service have already been weeded out as nearly as is humanly possible by the surgeons of the organizations to which they are attached, or by the Camp Board of Special Examiners.

PERSONAL

Capt. Bruce Ffoulkes, M. R. C., has been made director of field hospital companies, and Lieut. John D. Bartlett, M. R. C., has been made director of ambulance companies, of the Three Hundred and Fourteenth Sanitary Train, Eighty-Ninth Division. Lieut.-Col. Harry L. Boyer, M. C., has been appointed division surgeon of the Ninety-Second Division, and Captain Nicholls, M. R. C., formerly of the Presbyterian Hospital in Chicago, has been made his assistant. Lieut. Louis G. Harney, M. R. C., of wide industrial medical experience with the American Steel Foundries of East St. Louis, is assistant to the division surgeon of the Eighty-Ninth Division. Lieut. Judd H. Kirkham, M. R. C., of Langdon, N. D., is attending surgeon of the headquarters, Eighty-Ninth Division. Lieut. Albert G. Bower, M. R. C., formerly of the Department of Bacteriology, University of Chicago, is medical training officer of the Eighty-Ninth Division.

DISEASE CONDITIONS AMONG TROOPS IN THE UNITED STATES

Extracts from Telegraphic Reports Received in the Office of the Surgeon-General for the Week Ending Nov. 2, 1917

1. Total strength of troops	1,001,632
Admission rate per 1,000 (disease only) annual	955.2
Non-effective rate (all causes)	25.6
2. National Guard, strength	373,180
Admission rate per 1,000 all camps (disease only) annual	1,108.8
Non-effective rate all camps (all causes)	24.5

Camps showing admission rate for disease higher than average: Camps Kearney, Wheeler, Cody, Bowie, Sevier, Beauregard and Shelby.

Camps showing noneffective rate higher than average: Camps Wheeler, Bowie, Logan, MacArthur, Shelby, Beauregard, Sevier, Cody, Hancock and Kearney.

3. National Army, strength	426,578
Admission rate per 1,000 all camps (disease only) annual	929.8
Non-effective rate all camps (all causes)	20.1

Camps showing admission rate for disease higher than average: Camps Pike, Jackson, Dix, Dodge, Travis, Funston, Gordon and Lewis.

Camps showing noneffective rate all causes higher than average: Camps Pike, Dodge, Funston, Lewis and Dix.

4. Venereal Disease—

Admission rate Regulars	90.4
Admission rate National Guard (camps)	93.6
Admission rate National Army	135.6

Camps National Guard having rate above average: Camps Sheridan, Wheeler, Kearney, Logan, Sevier, MacArthur and Bowie.

Camps National Army having rate above average: Jackson, Pike, Custer, Dix, Lee, Travis and Meade.

5. Number of cases of pneumonia		228
Highest number in any one camp	Funston	22
Number of cases of meningitis		18
Highest number in any one camp	Funston	9

	Regulars, U. S. Army, in U. S. only, 1916		Regulars in U. S. week ending Nov. 2, 1917		Nat'l Guard, All Camps, week ending Nov. 2, 1917		Nat'l Army, All Camps, week ending Nov. 2, 1917

To Fort Oglethorpe, for a course of instruction, Lieut. HERMAN A. HEISS, Madison.

To New York City, Cornell Medical College, for a course of instruction in military roentgenology, from Fort Oglethorpe, Lieut. HARRY B. PODLASKY, Milwaukee.

To his home and the inactive list of the Medical Reserve Corps, from Washington University, St. Louis, Capt. GUSTAF R. EGELUND, Sturgeon Bay; from Camp Doniphan, Lieut. GEORGE G. RUHLAND, Milwaukee.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

CALIFORNIA

Personal.—Dr. Nolton N. Ashley, chief of the staff of the Oakland Emergency Hospital, has resigned, and has been succeeded by Dr. Charles H. Mackey.——Drs. Henry G. Brainerd, Charles L. Allen, Thomas J. Orbison and Edward H. Williams, all of Los Angeles, are the medical members of the board of trustees of the Psychopathic Association of California, elected at its annual meeting in Los Angeles, October 22.

Anthrax.—During August and September, according to the *Monthly Bulletin* of the state board of health there were eight human cases of anthrax in the state as reported to the board, and the state veterinarian has called attention to outbreaks among animals in Yolo, San Joaquin and Stanislaus counties and in remote sections of the San Joaquin and Sacramento valleys. In Yolo for a period the water in irrigating ditches was ordered shut off to prevent the possible spread of the disease by that means. Warnings have been given in regard to the handling of sick stock and the skinning of dead animals.

COLORADO

Personal.—Dr. Raynor E. Holmes, Canon City, has purchased the Goodloe Hospital, with a capacity of twenty beds, and will conduct it as a private hospital.—Drs. Wilbur T. Little and Hart Goodloe have entered on their military duties at Fort Sill, Okla., and Fort Riley, Kan., respectively.——Dr. Frederick A. Jackson, Salida, has been appointed physician and deputy coroner of Chaffee County, during the absence of Dr. Charles S. Phalen.——Dr. George B. Gilmore has been appointed assistant health officer for West Colorado Springs.

DELAWARE

Personal.—Dr. William P. Orr, Lewes, has been placed in command of the Marine Hospital at Lewes, succeeding Dr. George G. Hart, transferred.——Dr. John W. Mullin, Wilmington, has been appointed chief of the medical staff of the Delaware Hospital.

Typhoid Fever.—October 26, there were twenty-nine cases of typhoid fever in Wilmington which are known to have originated outside of that city. In addition, there are twenty cases which have been traced to one source in Wilmington. The supply of drinking water of the city is reported to be sanitary.

ILLINOIS

Personal.—Dr. Edward A. Glasgow was elected president of the First National Bank of Mulberry Grove, November 5. ——Dr. Edgar P. Cook, Mendota, has been appointed chairman of the cooperative committee to promote the antituberculosis campaign of the State Council of Defense.

Assignments to Health Officers.—The state director of health, Dr. C. St. Clair Drake, Springfield, announces the following assignments:

Dr. Clarence W. East, Evanston, relieved as medical officer for Camp Grant Health District, and detailed to investigate poliomyelitis in Cook County, and afterward to report for special assignment.

Dr. Arthur Pearman, Rockford, medical health officer to Camp Grant Health District, Rockford.

Dr. Alexander F. Stewart, Oneida, district health officer for the Western Health District, with headquarters at Galesburg.

Dr. John A. Kappelman, Evanston, relieved as medical health officer of Great Lakes-Fort Sheridan Health District excepting special assignment relating to water supply and sewerage disposal problems in North Chicago and Waukegan, and garbage disposal at Lake Bluff and Lake Forest, and detailed as health officer of the Northeast Health District, with headquarters at Chicago.

Dr. John A. Robison, Chicago, medical health officer of Great Lakes-Fort Sheridan Health District, with temporary headquarters at Lake Forest.

Dr. Charles E. Crawford, Rockford, medical health officer of the Northwest Health District excepting temporarily the Camp Grant District, with headquarters at Rockford.

Dr. Edward M. Irwin, Belleville, medical health officer for the Scott Field Health District, including the towns of Shiloh Valley and Belleville, in St. Clair County.

Dr. Charles S. Nelson, Springfield, medical health officer of the North Central Health District, with headquarters at Springfield.

Dr. Elbert L. Damron, Effingham, district health officer for the South Central Health District, with headquarters at Effingham.

Dr. John A. M. Gibbs, Unity, medical health officer for the Southern Health District, succeeding Dr. Isaac A. Foster, New Haven.

Chicago

Children's Hospital Profits by Rummage Sale.—As a result of the four days' White Elephant Sale, held in the old Calumet Club Building, November 7 to 10, $25,369 was raised for the Children's Memorial Hospital.

Personal.—Dr. Daniel N. Eisendrath read a paper on "Why Do We Have Recurrence of Symptoms After Operations on the Biliary Tract?" at the annual meeting of the Wisconsin State Medical Society, held in Milwaukee, October 3, and also read a paper on the same subject at the annual meeting of the Southern Illinois Medical Association, held at Murphysboro, November 1.

INDIANA

Tuberculosis Hospital Site.—The Madison County Council has appropriated $10,000 for the purchase of the site for a county tuberculosis sanatorium. A farm of 92 acres near Anderson has been selected for this purpose.

Endorse Wynn's Candidacy.—The Indianapolis Medical Society, October 27, adopted a resolution endorsing the candidacy of Dr. Frank B. Wynn for a member of the board of school commissioners, and paying high tribute to the ability and attainments of Dr. Wynn.

Personal.—Dr. Henry Jameson, Indianapolis, fuel administrator for Marion County, is the first director whose appointment has been formally recorded by the state administrator. ——Major Orange G. Pfaff, Indianapolis, will not be able to accompany Base Hospital Unit No. 32, on account of an injury to his knee.

IOWA

Honor to Rosenow.—At a gathering of representative citizens of Davenport, November 9, honor was rendered to Dr. E. C. Rosenow, in appreciation of his assistance during the recent epidemic of infantile paralysis in Davenport. An inscribed scroll stating the appreciation of his work, signed by the mayor and representatives of civic, social and medical organizations, was presented to Dr. Rosenow.

KENTUCKY

Personal.—Dr. Thomas F. Cleaver, Lebanon, sustained painful injuries when an engine ran into his automobile on a grade crossing, October 19.——Dr. John W. Gilbert, Lawrenceburg, while burning charcoal in a cistern, was overcome by the gas, and managed to get out of the cistern, but fell, sustaining painful wounds of the forehead.

MAINE

Health Department Reorganized.—The old state board of health, which was created in 1885, has been superseded by the state department of health, which was created by an act passed by the seventy-eighth legislature. Dr. Leverett D. Bristol has been appointed commissioner of health, and the state has been divided into health districts, each in charge of a district health officer.

Health Council.—The governor has nominated the following as the new Maine health council: John J. Ryan, Lewiston, probation officer; Eugene A. Cloutier, Lewiston, associate probation officer; Mrs. George F. French, Portland; Drs. Joseph E. Odiorne, North Whitefield; Robert J. Aley, Orono; Hiram W. Ricker, Poland; Sylvester J. Beach, Augusta, and Joseph B. Drummond, Portland.

MASSACHUSETTS

Personal.—Dr. Joseph A. Smith, police surgeon of Worcester, has resigned to enter the army service.——Physicians of Haverhill visted Georgetown, October 22, to pay their respects to Dr. Richmond B. Root, who celebrated the fiftieth anniversary of his entrance into the practice of medicine on that day.

Orthopedic Hospital for Boston.—The Order of Elks has made an offer to the city council of Boston to erect, for the federal government, an orthopedic hospital to cost $250,000, on the site of the old Parker Hill reservoir, provided the city will sell the site for $40,000. This is expected to be the first reconstruction hospital in the United States for crippled soldiers and sailors.

MICHIGAN

Tuberculosis Foes Meet.—At the annual meeting of the Michigan Anti-Tuberculosis Association, held in Battle Creek, Dr. William De Kleinie, Flint, was elected president, Drs. John H. Kellogg, Battle Creek, and Christopher G. Parnall, Jackson, vice presidents, and Dr. Henry J. Hartz, Detroit, secretary.

Personal.—Dr. William F. English, Saginaw, a member of the state board of health, will be stationed permanently at Battle Creek to assist the military authorities and the state board of health in the campaign to protect the health and morals of the soldiers at Camp Custer.——The University of Michigan has accepted the resignation of Dr. Claudius B. Kinyon, Ann Arbor; for twenty years professor of obstetrics and gynecology in the Homeopathic Medical School, and has appointed Dr. Theron G. Yeomans, St. Joseph, his successor.

Antituberculosis Notes.—Muskegon, Ottawa and Allegan counties are considering the proposition to build and operate a cooperative tuberculosis sanatorium.——At the meeting of the Michigan Anti-Tuberculosis Society, October 30, it was recommended that the state establish sanatoriums for men rejected from the National Army on account of tuberculosis who could be restored to health.——It is proposed to erect a joint tuberculosis sanatorium, to cost about $100,000, for the use of the six counties of Oakland, St. Clair, Livingston, Macomb, Washtenaw and Lapeer.——Members of the Delta County Board of Supervisors have approved the establishment of a joint tuberculosis society with Menominee, Dickinson and Iron counties.

MINNESOTA

Smallpox at Hamline.—There are now five cases of smallpox at Hamline University, Minneapolis. Practically all the students have been vaccinated.

Faculty and War Work.—Fifteen men and two women of the University of Minnesota faculty have been granted leave of absence by the board of regents to engage in war work for the government.

Navy Hospital School Opened.—October 29, the Navy Hospital Corps Training School of the University of Minnesota was formally opened, with an initial attendance of 100 Hospital Corps men from the Navy. The staff is supplied by the University of Minnesota Medical School.

Personal.—Dr. Jacob H. Stewart, St. Paul, was found unconscious on Summitt Avenue, St. Paul, November 1. He had apparently suffered a slight concussion of the brain.——Dean T. Frankforter of the College of Chemistry of the University of Minnesota was relieved of his administrative duties at his own request, October 25, and reduced to the rank of professor.——Drs. Clarence E. Lum, Duluth, and Walter Courtney, Brainerd, were severely injured by falling through a trap door at a hunting lodge in Ottertail County, October 25.——Dr. Walter R. Ramsey, St. Paul, will head a medical mission to France in January. Dr. Ramsey will take the place of Dr. Julius P. Sedgwick of the university, who is now in France organizing the work among children in the fighting zone.

MISSOURI

Tuberculosis Ward Opened.—The entire north wing on the fourth floor of the Kansas City General Hospital, which was formerly occupied as nurses' headquarters, is being remodeled, and will be used as a tuberculosis ward, accommodating about sixty-five patients.

Personal.—Dr. George P. Pipkin, Kansas City, who has been in Colorado for the past five months in search of health, has returned greatly improved.——Dr. Louis E. Newman, St. Louis, who had five ribs fractured in a collision between his automobile and a coal wagon, is reported to be convalescent.

Medical Inspection of Schoolchildren.—While medical inspection of the schoolchildren of Kansas City has been suspended by the municipal authorities for lack of funds, a public spirited citizen, who desires to remain incognito, has agreed to pay the expenses of the work for three months. Five physicians, five dentists and ten nurses will form the staff of inspectors and begin work at once under the supervision of the Hospital and Health Board.

Society Inaugurates Movement for Combining Laboratories of State Board of Health and State University.—At a recent meeting of the Boone County Medical Society, to which the members of Audrain, Gallaway, Cole, Cooper, Howard and Randolph County Medical Societies had been invited, resolutions were adopted in which were set forth the advantages of free laboratory work being done by the state university. It was proposed that the people of Missouri be made acquainted with the beneficial results of such a procedure, and that the next legislature be urgently requested to make the necessary appropriation for rendering the resolution effective.

First Class in Oral and Plastic Surgery Completes Course.—The first class of students from the Officers' Medical Reserve Corps ordered to take the course in oral and plastic surgery in the special school established at Washington University Medical School by the Surgeon-General of the Army has completed its course, the members, numbering thirty-seven, returning to their respective posts. The second contingent has reported for the course which began, November 5. There are thirty-five men in this class, of which twenty-seven are surgeons and eight are dentists. This course differs from the first in that it offers, in addition to oral and plastic surgery, surgery of the cranium and brain. Dr. Robert T. Frank, New York, is acting as military director.

Must Clean Up Vice Conditions.—Kansas City must clean up vice conditions at once or be quarantined against army camps is the edict of United States government officials. Mr. Henry F. Bart, in charge of the law enforcement department of the War Department, recently visited Kansas City and found conditions so demoralizing for the soldiers who visit the city from nearby camps that he ordered the immediate closing of all immoral houses, prohibiting women from soliciting on the street, and keeping all liquor away from soldiers. While the saloons have generally obeyed the law to refuse liquor to soldiers, the rooming houses and some hotels have permitted drinks to be served to soldiers in private rooms. The police department and the prosecuting attorney have promised to wipe out these vicious influences.

NEW HAMPSHIRE

Students Must Have Physical Examination.—The trustees of the New Hampshire College, Durham, have decided that hereafter every student on entering college must pass a physical examination.

Personal.—The residence of Capt. Charles A. Lamson, M. R. C., U. S. Army, at New London, was destroyed by fire, October 2.——Dr. Patrick J. McLaughlin, Nashua, has been appointed physician of Hillsboro County, succeeding Dr. Charles E. Congdon, who is in war service.

NEW JERSEY

Hospital Burns.—The Trenton Municipal Hospital, containing fifty-five patients, was burned, November 6. All the inmates escaped or were carried to places of safety, some of them being taken from the second floor by the staff of nurses, who for a times worked single handed in the mission of rescue. The loss is placed at $40,000.

Tri-County Physicians Elect Officers.—At the annual meeting of the Tri-County Medical Society, which includes, Cumberland, Salem and Gloucester counties, held at Millville, October 30, the following officers were elected: president, Dr. Harry A. Stout, Wenonah; vice presidents, Dr. Joseph N. Husted, Woodstown, and John H. Moore, Bridgeton, and secretary-treasurer, Dr. George E. Reading, Woodbury.

NEW YORK

Personal.—Dr. and Mrs. William N. Miller, Croton-on-Hudson, were seriously injured in a collision between their automobile and another car at Harmon-on-Hudson.——Dr. Marcus E. Babcock, Bath, was struck by an automobile, October 28, and received a severe wound of the scalp.——Dr. George F. Reusch, Franklinville, has accepted a position with the mining company at Virginia, Minn.

Commission Discusses Care of Insane.—The Hospital Development Commission, which was created by the last legislature to form a plan for the systematic enlargement of state institutions for the insane and feebleminded, recently conducted a hearing at the New York Academy of Medicine. The commission has presented the results of an investigation of the institutions for the care of the insane in this state and in Massachusetts, as well as in other states. The immediate establishment of psychopathic hospitals, especially in New York City, was urged. These hospitals should be employed simply as clearing houses to determine which persons might be restored by a short term of treatment and which should be sent to the state hospitals. The opinion was expressed that the care of the insane is properly a state function and should be kept so, as municipal governments were too likely to shift.

New York City

Woman Head of Parole Board.—Dr. Katherine B. Davis has been appointed chairman of the parole board by Mayor Mitchell. The term of office runs for ten years, with a salary of $7,500 a year.

Anniversary Address.—The anniversary address of the New York Academy of Medicine was delivered, November 15, by Dr. Henry Fairfield Osborn, L.L.D., president of the National Museum of National History, on "The Origin and Nature of Life."

Jamaica Hospital Opens Laboratory.—The Jamaica Hospital, Borough of Queens, announces that it has just completed the equipment of a roentgen-ray laboratory and is ready to render prompt and efficient service to the physicians of Queens who refer cases for roentgen-ray examination.

New York's Quota of Doctors for War Service.—The New York Chapter of the Red Cross has issued a statement asserting that when the base hospital units now awaiting a call to duty are in service, New York City will have sent 200 physicians and surgeons and more than 500 Red Cross nurses for war hospital work. The Presbyterian, Roosevelt, New York Port-Graduate, and the New York hospitals are already in service abroad. The other units, Bellevue, Mount Sinai, Herman and Metropolitan hospitals, have long been in readiness.

Medical Services Discuss War Problems.—Under the auspices of the New York State Committee, Medical Section of the Council of National Defense, a rally was held on the evening of November 9 at the Waldorf-Astoria, at which the heads of the medical services of the British and American governments discussed the probable requirements of the medical service. Dr. George D. Stewart presided at the meeting, and the principal addresses were made by Col. Sir Berkeley Moynihan, Major George W. Crile, Cleveland, and Dr. Franklin H. Martin, Chicago.

City Food Cabinet Organizes.—City Market Commissioner Henry Moschowitz has organized a cabinet of advisers drawn from the various city departments to consider the city's new undertaking of buying and selling food and fuel to the people. Work has been assigned to various city departments. The health department has as its task to make a study of wholesale and retail prices of essential commodities and the relation of these prices to the factors of distribution of trade. The Department of Public Charities is to study the relation of present prices to income. The members of this cabinet are to hold a conference each week to discuss ways and means of conducting their campaign to control, if possible, the high cost of living.

PENNSYLVANIA

Hospital Endowed.—The George F. Geisinger Memorial Hospital, Danville, built at a cost of $600,000 has now been endowed by Mrs. Geisinger for $1,000,000. A Scranton trust company has been named as trustee, the local board of trustees having been asked to resign.

Personal.—Dr. W. Rowland Davies, Scranton, has been elected president of the Craftmen's Club.——Dr. Adolph Koenig, Pittsburgh, October 1, was reappointed a member of the State Bureau of Medical Education and Licensure.——Dr. Adam L. Kotz, Easton, has resigned from the staff of St. Luke's Hospital, South Bethlehem, and has been appointed pathologist for the Easton Hospital.——Dr. Henry L. Orth, for twenty-seven years superintendent of the State Lunatic Hospital of Harrisburg, has resigned his position, to take effect as soon as his successor can be appointed.——Dr. Harvey L. Gerberich, Lebanon, was operated on in the Good Samaritan Hospital, in that city, and is reported to be convalescent.——Dr. Daniel Frederick, Ashley, who was operated on for appendicitis in St. Francis' Hospital, Pittsburgh, November 7, is reported to be doing well.

Philadelphia

Ambulance for Jefferson Base Hospital.—The West Philadelphia Auxiliary No. 4 of the American Red Cross presented a new field hospital ambulance to Base Hospital No. 38 of the Jefferson Medical College Hospital, November 7.

Reception to Moynihan and Crile.—At the stated meeting of the Club of Physicians in Philadelphia, November 7, the scientific business of the meeting was omitted on account of the reception to Sir Berkeley Moyihan, R. A. M. C., and Major George W. Crile, M. R. C., U. S. Army.

Plant Oak in Honor of White.—October 26, Arbor Day, in the presence of a notable group of representatives of business, professional and city life of Philadelphia, a red oak tree was planted in Rittenhouse Square in honor of the late Dr. William White, surgeon, author and nature lover.

Personal.—Dr. W. Wayne Babcock has been appointed chief surgeon of the base hospital at Fort McPherson, Atlanta, Ga.——Dr. Clarence P. Franklin, adjutant of the Allentown training camp, has been promoted from major to Lieutenant-Colonel.——Dr. Richard M. Pearce, professor of research medicine, University of Pennsylvania, has been made director of the recently established bureau of medical service of foreign commissions of the American Red Cross.——Dr. Edward A. Schumann has been elected lecturer on obstetrics in the Jefferson Medical College.——Dr. Mary D. Ridgeway, Germantown, was seriously burned, October 17, by the explosion of a lamp.——Dr. Hubley R. Owen has been given an indefinite leave of absence as chief of police surgeons of Philadelphia. Dr. Owen is an officer of the Medical Reserve Corps, and is connected with the Jefferson Hospital Unit.

School of Oral Surgery Opens.—November 10, Provost Smith of the University of Pennsylvania announced that a new course for army dentists and surgeons had been established at the Evans Dental Institute, Fortieth and Spruce streets, under the direction of Dr. Charles K. Turner, dean of the dental school.——Thirty-two advanced students, who are not only practicing physicians and surgeons, but who are at present actively engaged as officers of the Medical and Dental Corps of the Army, have been detailed to Philadelphia for the school. The course will continue during the period of the war. While the University Dental School has been designated as the headquarters of the course, some of the branches and laboratory work are being done at the Jefferson Medical College, Jefferson Hospital, Baugh Institute of Anatomy of the Jefferson College, Medico-Chirurgical Hospital, Philadelphia General and the Pennsylvania.——The commissioned officers sent to the school from the United States Dental Corps are: surgeons: Major E. J. Johnson, Capts. R. E. Balch, Carl Eggers, A. P. Roope, R. C. Wiggon; Lieuts. Ivan R. Burket, Bernard Friedlaender, S. D. Gleeton, C. W. Hoffman, R. M. Kleckner, F. Koontz, A. J. McCracken, W. H. Maley, J. W. Means, Samuel Oast, Jr., Howard Schriver and E. M. Vaughan. Dental surgeons: Lieuts. Vincent E. D. Bragg, R. S. Catheron, H. O. Cowles, F. H. Cushman, H. T. Hinrici, W. H. Hynard, C. J. Meyer, G. C. Parry, S. D. Ruggles, W. J. Scruten, I. E. Smith, J. D. Stone, C. W. Swing, C. E. Waters, J. B. Williams and P. J. Wumkes.

CANADA

Officers Wounded.—The following officers of the Canadian Army Medical Corps were recently reported wounded: Lieut.-Col. Anson S. Donaldson, Calgary, Alta.; Capts. James E. Bloomer, Moose Jaw, Sask.; J. Harold Jones, Vancouver, B. C.; Richard W. Kenny, Winnipeg, Manit.; Robert Mackenzie, Vancouver, B. C., and James Moore, Listowel, Ont.

Medicated Wines.—The Ontario License Board is instituting an active campaign against the "medicated wines." According to an amendment to the Patent Medicine Law recently passed at Ottawa, the board can now proceed with prosecutions under the Ontario Temperance Act, which carries a maximum penalty of $1,000 fine. It is understood that the board will proceed direct against the manufacturers and not the druggists.

Notification of Venereal Diseases.—The Board of Health of Toronto, through Dr. Charles J. C. O. Hastings, will ask the Ontario Board of Health to have all persons with venereal disease placed under quarantine, as is the case with all other communicable diseases. They will also seek legislation to provide for any one suspected of being infected undergoing an examination, and, if found diseased, quarantined, the board of health to have the final decision in case of dispute.

Canadian War Cripples.—Douglas C. McMurtrie in *The Survey*, Nov. 3, 1917, gives an account of the work done by the Military Hospitals Commission and allied organizations and officials in Canada for the training of soldiers crippled in the war. This work is now well organized in Canada and decided progress is being made. McMurtrie describes particularly the work in Alberta in the Ogden Military Convalescent Hospital, near Calgary, and also at Edmonton, where well equipped institutions are carrying on this work.

Fee-Splitting in Toronto.—Dr. D. J. Gibbs-Wishart, president of the Academy of Medicine, Toronto, took occasion to rap fee-splitting in his presidential address before that body:

"It is a frankly dishonest transaction which stamps as a fraud the practitioner who demands his pound of flesh." He stated he was credibly informed that men in Toronto had endeavored to solicit the operative work of practitioners on the frankly stated basis of a fifty-fifty division of the fee. He, even—specialist in nose and throat—had been personally solicited by a general practitioner to state what percentage he might expect to receive on referred cases.

Scarcity of Doctors in Canada.—Dr. John W. Edwards, ex-member of parliament, Cataraqui, Ont., says that medical students should be exempted from the military service. Medical officers point out that the public does not realize the scarcity of doctors in Canada at the present time. It is understood that the government intends issuing authority to the exemption boards to allow medical students to continue their studies, in view of the fact that the War Office has sent back to Canada to finish their course second and third-year men of Queen's, Toronto and other medical colleges, who were serving in various capacities overseas.

Cancer in Canada.—Dr. Charles J. C. O. Hasting, M. O. H., Toronto, estimates there are between 7,500 and 8,000 deaths from cancer in Canada every year, and the majority of these, 80 to 90 per cent., are of persons over 40 years of age. Three quarters of those lives might be saved by early diagnosis and proper treatment. He sounds a note of warning to the public and says that as there is no known medical cure for cancer there is therefore no worse criminal than the man who advertises to sell a cure for cancer (or consumption), as he is robbing the victims of their only chance for recovery—early eradication, radium or roentgen-ray treatment.

Hospital News.—Some time ago the Hamilton (Ont.) City Council appropriated $60,000 to $70,000 for remodeling the administration building of the Hamilton City Hospital, but had held back the money. Last week a conference took place between the hospital governors and the board of control, but they failed to come to an agreement as to the absolute necessity of the alterations at the present time.——The Military Hospitals Commission of Canada has decided on the immediate erection of a convalescent home for returned soldiers at London, Ont. Provision will be made for 300 beds, and arrangements will be made later on to expand to a capacity of 600 beds. The Ontario government will bear a substantial proportion of the cost of construction.

Medical Inspection of Schools in Toronto.—The system of medical inspection of schoolchildren now in operation in Toronto provides for inspection in the separate (R. C.) schools as well as the public schools, and for all the year round, instead of for ten months of the year, as formerly. Dr. Marchant B. Whyte, who was superintendent of the Isolation Hospital, has been placed in charge of the work under Dr. Charles J. C. O. Hastings, the former being director of medical services. Under the arrangement the health physicians employed in the schools are required to carry out the duties of medical officers of health, each being assigned a district—the city having been divided into several health districts, five in number, and under this arrangement, likewise, the public school nurses have been incorporated into the general public health nursing system of the city.

Personal.—Capt. John M. Adams, C. A. M. C., who has been overseas for two years, has been recalled to Ottawa for special duty in the department of documents.——Major Andrew Macphail has arrived in Montreal from overseas.——An escaped prisoner from Germany has brought word of the Hon. Dr. Beland, formerly postmaster-general of Canada. He is in good health, but has lived regularly in prison since June last. He is allowed out twice weekly under guard. He gives his medical services freely among the British prisoners and maintains a kitchen at his own expense, and is a very efficient cook. Dr. Beland was not told of the death of his wife until three days thereafter, apparently so that he would not have a good excuse to ask to go to her funeral.——Dr. William H. Hattie, Halifax, N. S., was elected president of the Canadian Public Health Association at its recent meeting.——Dr. Frederick S. Minns, who was acting medical inspector in chief of the board of education in Toronto when it was transferred to the Department of Public Health, has resigned.——Drs. Norman E. McKay, M. O. H., Halifax, N. S., and Napoleon Boucher, M. O. H., Montreal, Que., have been members of a special committee under the food controller, inquiring into the milk supply of Canada.——Capts. Charles A. Temple and William J. Clark and Major W. Harley Smith, Toronto, who have been in England for two years, have returned.——Lieut.-Cols. Irving H. Cameron, Toronto, Clarence L. Starr and John D. Courtnay, Ottawa; Major Donald McGillivray, Toronto, and Dr. Robert B. Wilson, roentgen-ray expert, Montreal, have started from Halifax to make an official visit of inspection of all the military hospitals of Canada from coast to coast.——Capt. H. A. Simkins of the Spadina Military Hospital, Toronto, has been transferred to England.——Dr. J. Gordon Gallie, Toronto, has resumed practice after service abroad.——Capt. Andrew S. Moorhead, Toronto, is now doing surgery in France under Lieut.-Col. Herbert A. Bruce, Toronto.——Capt. Roland W. Young, Oshawa, Whitby Military Hospital, has been transferred to the Toronto Military Base Hospital.——Major Andrew Macphail, Montreal, editor of the *Canadian Medical Association Journal*, has gone to visit his old home in Prince Edward Island.

GENERAL

Correction.—At the Physicians' Club banquet to Dr. Billings, described last week, it was stated that Governor Lowden was introduced by Dr. A. M. Corwin and that Dr. Arthur O'Neil acted as toastmaster. Dr. A. Augustus O'Neil acted as toastmaster and introduced Governor Lowden.

Correction.—In publishing the list of chiefs of the medical service in the cantonment hospitals in THE JOURNAL for Oct. 20, 1917, Major William S. Bigelow of Boston was given as the chief of the service of Camp Cody, Deming, N. M. This should be Major Edward B. Bigelow of Worcester, Mass.

Paul Jones Club Officers.—At the annual meeting of the Paul Jones Club, Sons of the American Revolution, held at Portsmouth, N. H., November 7, Dr. Henry I. Durgin, South Eliot, Me., was elected president, and Drs. William O. Junkins, Eugene B. Eastman, Portsmouth, and Fred S. Cowle, Portsmouth, were elected members of the board of managers.

Ohio Valley Physicians Elect Officers.—At the nineteenth annual meeting of the Ohio Valley Medical Association, held in Evansville, November 7, the following officers were elected: president, Dr. J. Rawson Pennington, Chicago; vice presidents, Drs. Walter F. Boggess, Louisville, Ky.; Meyer L. Heidingsfeld, Cincinnati, and Virgil H. Moon, Indianapolis, and secretary-treasurer, Dr. Benjamin L. W. Floyd, Evansville (reelected).

Eye, Ear and Throat Men Meet.—At the twenty-sixth annual meeting of the American Academy of Ophthalmology and Oto-Laryngology, held in Pittsburgh, October 29 and 30, the following officers were elected: president, Major Allen Greenwood, M. R. C., U. S. Army, Boston; vice presidents, Drs. Virginius Dabney, Washington, D. C.; Frank R. Spencer, Boulder, Colo., and W. Likely Simpson, Memphis, Tenn.; secretary, Dr. Lee Masten Francis, Buffalo, and treasurer, Dr. Secord H. Large, Cleveland.

Bequests and Donations.—The following bequests and donations have recently been announced:

University of Pennsylvania, $600,000 from the executors of the will of Eckley B. Coxe; of which $500,000 is to be used for the Unversity Museum, and $100,000 for the pay of professors and keepers.

St. Luke's Hospital, Bethlehem, a gift of a ward, costing $90,000, from the Bethlehem Steel Company, October 18.

The Board of School Commissioners, Indianapolis, his medical laboratory for the use of physicians and others needing information, and the Presbyterian Board of Missions, his instrumental and surgical equipment by the will of Dr. John Kolmer.

St. Bartholomew's Clinic, New York, $10,000; the Morristown (N. J.) Memorial Hospital, $100,000; Germantown Dispensary and Hospital, $100,000; St. John's Guild, New York, $50,000, and Babies Hospital and St. Mary's Free Hospital for Children, New York, each $100,000 by the will of Mrs. Mary Warden Harkness.

St. John's Guild and Hebrew Orphan Asylum, New York, each $500, by the will of Joseph Morningstar.

Augustana College, Rock Island, Ill., his library, by the will of Dr. Carl Oscar Bernhardi, Rock Island.

FOREIGN

De Quervain Succeeds Kocher.—F. de Quervain, now professor of surgery at the University of Basle, has accepted a call to the medical faculty of Berne as successor to Kocher.

Jadassohn Called to Succeed Neisser.—J. Jadassohn, who has been professor of dermatology at the University of Bern since in the nineties, and is said to have been practically the founder of dermatology in Switzerland, has now gone to Breslau to take the chair left vacant by the death of his old teacher, Neisser, some months ago. He was born not far from Breslau, in 1863.

Beretta Prize for Milan Physicians.—Dr. A. Beretta of Milan bequeathed to the city of Milan a fund of $40,000, the income of which is to be awarded as a biennial prize for the best work on clinical medicine or pathologic anatomy done during the two years by some physician who has resided in the province of Milan for at least five years, but has not been in practice longer than twelve years. The money prize is to be accompanied with a gold medal.

Memorial to Gutierrez of Madrid.—A statue of Gutierrez, Count of San Diego, was recently unveiled on the grounds of the Rubio Institute at Madrid, three years after the death of this leader in gynecology in Spain. Among the speakers, Cortezo, president of the Academia de Medicina and editor of the *Siglo Medico*, classed Gutierrez with Letamendi and Cajal as Spain's great modern trio. He remarked further that the fame of the practitioner is ephemeral, even the best beloved, but a monument prolongs it and thus makes up in part for the inadequate compensation which the fees for his visits represent in return for the persevering devotion and self abnegation which the practice of medicine signifies.

Deaths in the Profession Abroad.—Sir David Caldwell McVail, Glasgow, Scotland; L.F.P.S. (Glas.), 1866; L.R.C.P. (Edin.), 1866; M. B. University of Glasgow, 1876; aged 72; formerly professor of clinical medicine in St. Mungo's College, Glasgow; physician to the Glasgow Royal Infirmary; Crown member for Scotland of the General Medical Council; a member of the Court of Glasgow University, since 1891; a prolific writer on the mechanism of respiration and diseases of the respiratory organs; died at his home in Glasgow, November 4.——**E. Huet**, one of the pioneers in electrology in France, aged 57. He had charge of the electrotherapeutic department at the Salpêtrière, and the account of his work and honors is practically the history of electrodiagnosis during the last twenty-five years.——**Lieut.-Col. F. E. Viana**, professor of surgery at the Medico-Military School at Mexico City.——**P. Malerba**, research worker and professor of physiologic chemistry at the University of Naples, aged 68.——**D. Sangrador** of Madrid, killed in a railroad accident while on his way to the recent medical congress at Valladolid.——**J. Rambousek**, professor of factory hygiene at the University of Prague, and an authoritative writer on industrial poisonings.

LONDON LETTER

London, Oct. 23, 1917.

The War

MINISTRY OF HEALTH POSTPONED

The prime minister, Mr. Lloyd George, received a deputation from the joint committee of approved societies and the conference of the Amalgamated Society of Industrial Assurance, representing about 12,000,000 insured persons. The objects of the deputation were: 1. The early establishment of a ministry of health on lines satisfactory to national health insurance organizations. 2. The early passage into law of a bill for the simplification of insurance administration. 3. The financial readjustment of national health insurance by a further grant. The premier said that the exchequer was not in a position in the middle of a great war to make the same promises in regard to insurance or any other social projects that it could very well make in days of peace. Our energies and our thoughts had been taken away from projects for the amelioration of the condition of the people to the terrible demands made on us in the defense of our liberties. The drain on our resources was unparalleled, and we were not at the end of the charge on our national wealth. He wished he could predict that we might soon see the end of it, but the task which the nation had taken in hand must be accomplished. Otherwise not merely the power and prestige of this nation were broken, but its future was pretty hopeless. We must husband our resources and incur no obligations beyond the strictest and sternest necessities of the hour, and when demands were put forward for improvements here and there, his answer would be, "Concentrate on victory." For the moment every claim on the exchequer must be considered in the light of the terrible possibilities of the war; and when it was over, in a freer and happier atmosphere we could begin to rebuild, reconstruct and regenerate. As to the bill for a ministry of health, Mr. Lloyd George said he was the last person to contend that it was not an urgent measure. We had to repair the ravages of the war. Stricter attention to the health of the community and to the saving of life by that means was one of the most efficient and surest methods of attaining that end. The damage would be great, even if the war was arrested now. The losses would be beyond count; and we should have to devote resolution, courage and readiness to find an agreement which this war had disclosed rather than seek for a point of controversy—we should have to apply the whole of that new spirit to proposals of this kind. Otherwise we should never repair within our day, nor within the day of our children, the ravages of this great war; but if we did concentrate in that spirit we should not merely clear the débris of war, we should not merely restore, but we should build something stronger, grander and on a firmer foundation than we had ever witnessed. He was certain that in one form or another we must drastically reform the administration of our health laws. There were conditions that were incompatible with health. It was a scandal that a nation which had shown such capacity for meeting great emergencies should have lethargically tolerated conditions of that kind. It was regrettable that people capable of the sort of explosive energy which this country had put forth in two or three years should have allowed slums, misery, and wretchedness and squalor to drain the land. We wanted people who enjoyed liberty to be fit to defend it, and that was one of the problems of the future.

THE MEDICAL TREATMENT OF INVALIDED SOLDIERS

The Army Council has issued revised instructions relating to the continued treatment and training of soldiers discharged from the army on medical grounds. Two categories of patients are contemplated in these instructions: (1) soldiers who at the actual time of their discharge require further treatment, and (2) soldiers who at some time after their discharge are found to require further treatment. This category is confined to men suffering from ailments arising from wounds or injury sustained during military service. As a general rule, the patients to whom these instructions apply will be those suitable for treatment as outpatients in hospitals, because army regulations in force already provide that so long as inpatient treatment is required, soldiers shall not be discharged from hospital. It is foreseen, however, that in certain special cases, as in tuberculosis or paraplegia, further inpatient treatment may be necessary. The further treatment thus to be afforded will be available at military Red Cross hospitals through agency of the local war pensions committees. In order that the local committees may efficiently carry out the duties devolving on them, they are to be furnished with cards, recording all relevant information relating to men about to be invalided out of the army. These cards will indicate whether or not further treatment is needed, and, if so, where it may be obtained. The committees will also be empowered to appoint hospital visitors, to visit and confer with the hospital authorities—or the medical authorities at command depots and camps—responsible for men about to be invalided out. In addition to treatment, special courses of technical training may in many cases be desirable. Patients for treatment in the second of the two categories described above must themselves make application in the first instance to the local committees. After ascertaining the eligibility of the applicant, the committee will send him to a military hospital for examination. The hospital will furnish a card, as described above, giving authority for the further treatment of the applicant.

FOOD ECONOMY

Sir Arthur Yapp, president of the Y. M. C. A., has undertaken the direction of a new food economy campaign, which is necessary in view of the dearth of many of the principal foods. Next month a flood of oratory is to be let loose throughout the country. A committee of experts in the food controller's department is working out a scientifically graded scheme of rationing. Taking into consideration the available supplies of food and the needs of our allies, they are seeking to find out exactly what each man, woman and child ought to have according to age and occupation and other relevant circumstances. As soon as they have reached decisions, the scale of consumption which they recommend will be made known. The rationing will be for all essential foods. It will be our task to see that the scale is observed. In addition it will be necessary to ask people occasionally to make a definite sacrifice and for a time to go without some particular thing altogether. Sir Arthur Yapp is endeavoring to establish a league or committee of national safety to bring home to the people that our national safety and the allied cause generally depend on the extent to which we economize in food consumption. The first members of the league will be asked to do everything possible to educate others. They will be asked to pledge themselves to live within the scale of rations laid down and to avoid waste. It is hoped to evolve a scheme to keep in touch with members so that once a month points for use in the campaign can be sent to them.

THE NATIONAL HEALTH IN 1916

The report for 1916 of Sir Arthur Newsholme, medical officer of the Local Government Board, has just been issued.

A review of the national health of the present time is rendered exceptionally difficult by the disturbances of population due to the war and to the gigantic new industries which have been created. So far as ordinary infectious diseases are concerned, with the exception of measles, the record of 1916 has remained favorable. There have been no cases of cholera. The tuberculosis work of local authorities during the year has been further restricted by the war. One of the most urgent of after-war problems will be to secure the early resumption and extension of this work, particularly in regard to the provision of greatly increased hospital accommodation for persons with advanced cases of consumption. The reduction in the number of births emphasizes the importance of saving child life and of improving the health of all survivors. Sir Arthur Newsholme considers that there is no insuperable difficulty in reducing the total deaths in childhood to half their present number. During 1916 the rate of infant mortality was the lowest on record. Owing to a large proportion of health officers having been released for military service, an increasing number of women physicians have been appointed for public health work, the depletion of the services having become serious. Unless considerable readjustments are made, more officers cannot be spared for the army consistently with the public safety. The staffs of inspectors of nuisances had also been greatly depleted, and many untrained men and women are performing duties formerly in the charge of trained men. It is not surprising that under these conditions, outbreaks of infectious diseases in a few instances have not been promptly controlled, and that, especially in regard to smallpox, enhanced risks have been, and continue to be, incurred owing to the inexperience of the local officers. A large part of the time of those medical inspectors who are not on military duty is taken up in emergency work arising out of the foregoing considerations. Health officers and sanitary inspectors remaining on civil duty have done admirable work in assisting less experienced temporary colleagues in other districts. In a not inconsiderable number of instances, one officer has acted for several areas in addition to his own.

PARIS LETTER

PARIS, Oct. 18, 1917.

The War

RESULTS OF ANTITYPHOID AND ANTIPARATYPHOID VACCINATION OF THE SOLDIERS DURING THE WAR

An interesting communication on this subject was read by Prof. H. Vincent at a recent meeting of the Académie des sciences. He said that in the present war, during the winter of 1914-1915, a very severe, rapidly progressing epidemic had made its appearance. Because of the exigencies of war, preventive vaccination could not be made effective at the front during that period. A less serious recurrence of paratyphoid took place during the fall of 1915. Since then the armies at the front have enjoyed an unusually good state of health. Typhoid and paratyphoid have existed only in a very slight degree, in spite of the presence of the aggravating conditions of exceptional severity brought about by a violent and prolonged war; by the mobilization of large numbers of troops, such as have never been observed before in any war; by the constant arrival of new troops; by the close contact of many men, thus increasing the danger of direct and indirect contact through the agency of the sick, as well as by carriers; and by the flies and the continual contamination of the soil.

The wholesale vaccination of the troops at the front was commenced in February, 1915. Since the beginning of the war the laboratory of the army has sent to the front 5,513,073 doses of vaccine. Before the war and since the year 1911, 20,000 soldiers have been vaccinated against typhoid and paratyphoid A and B with mixed or triple vaccine; 200,000 others have been vaccinated against typhoid only. At the present time, thanks to this active immunization, these diseases can be considered as having been practically vanquished. From 6.12 in November, 1914, 7.24 in December, 1914, and 7 in January, 1915, per thousand men, the number of cases dropped rather suddenly to 4.3, 2.49 and 1.6. In August and September, 1915, the morbidity (paratyphoid predominant) rose to 2.47 and 2.65, but since then it has diminished more and more. During February, 1916, the percentage of cases per thousand was less than 1, and this percentage has been maintained. In 1917, the monthly rate was: 0.1, 0.048, 0.025, 0.028, 0.036, 0.064, 0.068 and 0.063 per thousand. As for the mortality, from the fastigium of the 1914-1915 epidemic (November to March), the curve descended almost vertically to the present time. The vaccination by two injections is responsible for this remarkable recession in the number of cases and deaths, and the mortality is now so low that one is obliged to evaluate on the basis of 100,000. Even when we reduce to that scale, the percentage is often fractional. In 1917, it has been successively 0.6, 0.5, 0.5, 0.1, 0.3, 0.6, 0.4 and 0.3 per hundred thousand.

The value of this specific prophylactic measure cannot, in fact, be determined precisely. If the morbidity and mortality of these typhoid diseases as observed from November, 1914, to January, 1915, had been maintained, one could estimate, on the basis of 4 or 5 million soldiers having been sent to the front during the thirty-eight months of the war, that the number of cases of typhoid would have exceeded a million, with 145,000 deaths. This is not taking account of the aggravating influences obtaining during the war and the unusual weather conditions of the fall months of the three years during which this war has been waged; consequently, this preventive vaccination may be credited with having been of immense economic value to the army as well as to France as a whole. Taking for comparison the health of the French army before the war, as set forth in the official statistics for the year 1911 (the last published), it will be seen that at present the number of cases of typhoid fever occurring in the armies at the front are more than seven times less numerous, and that the number of deaths is 8.5 times less numerous than during peace times.

SHELL FRAGMENT IN THE LEFT AURICLE

At a recent session of the Académie de médecine, Dr. Le Fort reported an observation made on a wounded soldier from whose left auricle he extracted a piece of shell the size of a pea. Of the six walls of the left auricle, only one is accessible, the postero-inferior, the narrow space bounded by the pulmonary veins, the auricular appendage and the auriculoventricular vessels. The shell fragment had been fixed with the fingers in a fold of the auricular wall; two loops of thread were passed at the base of the fold. Then the auricle was incised with a bistoury, the fragment extracted and the threads tightened. Complete hemostasis was effected. The patient died on the fourth day. The necropsy showed that the sutures had held perfectly, that there had been no hemorrhage in the pericardium, and no blood clots were found in the heart. The patient was 45 years of age, and he had recovered from a pulmonary affection shortly before he was wounded. The intrapleural space was entirely obliterated. The heart was small and fatty, with fatty perinephritis of the right kidney, slight hydronephrosis of the left, etc. Dr. Le Fort has thus far performed seven operations for the extraction of foreign bodies from the heart, and four pericardial extractions with one death and ten recoveries.

Repression of Public Drunkenness

October 1, a law, dealing with the repression of public drunkenness and the supervision of saloons, was promulgated. This law imposes on persons found in a manifest state of drunkenness on the streets a fine of from 1 to 5 francs for the first offense. The second offense is punishable by from one to three days' imprisonment, and a third offense, when occurring within the first twelve months, is punishable by imprisonment for from six days to one month or a fine of from 16 to 300 francs. Any person who is convicted twice may be deprived of his electoral and civic rights for two years. The law fixes an analogous penalty for such dealers as shall serve liquors to minors (under 18), and dealers who are fined more than once will be liable to closure of their establishments for a year or more. The sale of alcoholic liquors on credit is interdicted. The law forbids the employment of females under 18 years of age in retail liquor establishments, unless they are members of the proprietor's family. Dealers who encourage debauchery shall be imprisoned for from six days to six months, and shall forfeit their political rights for five years. Their establishments shall be closed permanently.

Treatment of War Fractures

At one of the recent sessions of the Société de chirurgie of Paris, Dr. Heitz-Boyer, chief of the surgical clinic of the Faculté de médecine de Paris, described the organization and method of procedure of the Fracture Center at Châlons-sur-Marne, of which he is director. This center was established for the following reasons: (1) to assure patients, whose condition often demands many months of hospital residence, of continued care under conditions which must obtain if the surgeon is to assume full responsibility; (2) to provide that the care is always given in a center of this kind properly equipped from the point of view of the necessary material organization, apparatus and procedure; (3) to institute such care as early as possible, endeavoring to keep in mind the military as well as the surgical needs; (4) to assure the evacuation of these patients at the earliest possible time to the next unit formation within the same surgical group.

From the application of these principles has been born the special surgical "bone group" in each army, consisting of three grades or divisions, comprising the principal formations situated in the rear of the lines where operations are performed. Farther back in the interior are two branches, the first known as the second hospital, where the discharged patients, or those who are out of danger, are hospitalized until such time as the wounds have healed and the bones have united; and a second, known as the division of physiotherapy where the convalescents and those who are to be discharged from the army on account of disability receive such care as will restore to them as much function as their injury permits. Therefore, the treatment of the wounded is always under the surveillance and direction of a single responsible head. All records are carefully kept and interchanged, so that complete observations may be made, and the value of different procedures employed by the single units may be compared. Finally, from a material point of view, each group can be so well equipped that all kinds of work can be done, the equipment sufficing to take care of the wounded in the different stages of their illness. The apparatus accompanies the wounded into the different relays of the entire course. The results obtained by Heitz-Boyer in his center, where he has treated, since April, nearly 700 cases of fracture, more than 100 of these involving the thigh, have been so good that the value of this team-work method is fully attested.

New School for the Reeducation of Disabled Soldiers

The president of the republic recently visited a new school for the vocational reeducation of the mutilated, founded by the Union of Foreign Colonies in France in the Ferme de Champagne at Juvisy-sur-Orge for the benefit of war victims. The new school was founded exclusively for the benefit of mutilated or wounded agriculturists. It includes sections for general training, horticulture, nurseries, agricultural mechanics and automobile traction. Since the opening of the school, 550 patients have been admitted. A large number have been returned to their homes, properly benefited; for the others, lucrative positions have been obtained by the union. The principal workers in establishing these foundations, in which cooperated American, English, Dutch, Norwegian, Russian and other committees, constituting the Union of Foreign Colonies, are: Mm. Ascher, L.-V. Benet, L. Kone and B.-J. Shoninger, vice presidents.

The Bread Card and the Composition of Bread

Commencing October 15, a rigorous bread card régime was instituted. The maximum quantity of bread allowed for the weekly consumption of each individual was fixed on the following basis: for persons from 1 to 6 years of age, 300 gm. per day; more than 6 years of age, 500 gm. In addition, a flour ration of 50 gm. per day is provided for infants under 3 years of age; on the other hand, a supplementary ration, not exceeding 200 gm. per day, is allowed for all persons who shall make satisfactory declaration to the effect that such addition is indispensable to their nourishment. A second supplementary ration, not to exceed 200 gm., is allowed to persons engaged in hard work, and whose food consists largely of bread.

The composition of bread provoked an interesting discussion in a recent session of the Académie de médecine. The following resolutions were adopted: (1) the miller must grind only grain which is sound, free from foreign bodies and altered grains, that is, good and not damaged grain; (2) the percentage of the boltage cannot be uniform; it necessarily must vary with the quality of the grain, as determined by the weight of a hectoliter (2¾ bushels); (3) acting on the directions so far received, it seems that the present regulations in vogue have brought about the distribution of bread which has in a certain number of cases caused some illness; (4) the method of making bread with lime water, besides having many advantages, does not seem to cause any inconvenience from the health standpoint; (5) in regard to substitutes for cereals, it is very desirable to use rice in the French diet as much as is possible. Rice flour, as well as barley, rye, buckwheat and corn flour can be added to wheat flour for bread making. If well prepared, these flours do not give rise to any untoward effects.

Association News

THE CHICAGO SESSION

Local Committee on Arrangements for the Chicago Session of the American Medical Association

The following constitute the Local Committee on Arrangements for the session of the American Medical Association to be held in Chicago, June 10-14, 1918: Drs. Ludvig Hektoen, chairman; Charles J. Whalen, secretary; W. A. Pusey, John V. Fowler, Hugh T. Patrick, M. L. Harris, Charles F. Humiston, J. B. Herrick and Frank Billings.

Marriages

Lieut. Philip Emerson Thomas, Jr., M. R. C., U. S. Army, Camp Beauregard, Alexandria, La., to Miss Louise Walls of Holly Grove, Ark., October 28.

Samuel Lutz Zurmehly, M.D., Rushsylvania, Ohio, to Miss Ethel Long of Kingston, Ohio, at Chillicothe, Ohio, October 26.

Major Arthur Wells Elting, M. R. C., U. S. Army, Albany, N. Y., to Mrs. Francis W. Rawle of Bryn Mawr, Pa., October 25.

Walter Scott Patterson, M.D., Butler, Pa., to Miss Gertrude Connors of Penn Township, at Butler, October 24.

John Thomas Sullivan, M.D., Milwaukee, Wis., to Miss Lona Chapman of North Fond du Lac, Wis., October 27.

August Edward Witzel, M.D., Utica, N. Y., to Miss Helen Marguerite Van Alstyne of Ilion, N. Y., October 24.

Robert Morton Manson, M.D., San Leandro, Calif., to Miss Madeline Strohl of Oakland, Calif., October 31.

John C. Reed, M.D., Duquesne, Pa., to Miss Lillian Bennethum of Harrisburg, Pa., October 24.

Peter Burrell Mulligan, M.D., Hazleton, Pa., to Miss Helen Leonard of Camden, N. J., recently.

Audley Durand Stewart, M.D., Rochester, N. Y., to Miss Jane Walker Russell of Chicago, recently.

Walter Martin Skallerup, M.D., Walker, Iowa, to Miss Belle Forrester Black of Chicago, June 27.

Pattison Albert Waters, M.D., Monte Vista, Colo., to Miss Ethel Keen of Denver, October 7.

Deaths

Newell Bly Burns, M.D., North Wilmington, Mass.; Harvard Medical School, 1909; aged 35; a Fellow of the American Medical Association, and a member of the National Association for the Study and Prevention of Tuberculosis and the American Sanatorium Association; assistant superintendent and physician to the North Reading (Mass.) State Sanatorium for Tuberculosis; instructor in pulmonary diseases in Tuft Medical School, Boston; died in the sanatorium, October 27, from rheumatic endocarditis.

Harris Gray Sherman, M.D., Cleveland; College of Physicians and Surgeons in the City of New York, 1880; aged 61; a Fellow of the American Medical Association, and a member of the American Academy of Ophthalmology and Oto-Laryngology, and American Ophthalmological Society; a specialist on diseases of the eye; first medical inspector of schools of Cleveland; at one time president of the Cleveland Chamber of Commerce; died in Charity Hospital, Cleveland, October 30, from pneumonia.

Francis L. Springer, M.D., Newport, Del.; University of Pennsylvania, Philadelphia, 1877; aged 63; formerly a Fellow of the American Medical Association; a member of the Delaware State Medical Society, and its president in 1912; for nine years trustee of the poor, and once a member of the visiting staff of the State Hospital, Farnhurst; for several terms physician of New Castle County; died suddenly at his home, October 24, from cerebral hemorrhage.

Lieut. George Walter H. Conrad, M. R. C., U. S. Army, Philadelphia; Hahnemann Medical College, Philadelphia, 1913; aged 29; a specialist on diseases of the eye, ear, nose and throat; who had been on duty at Fort Benjamin Harrison, Ind., until August 27, when he was transferred to the aeronautical school at Austin, Texas; died in the Army Base Hospital, San Antonio, Texas, October 30, from abscess of the brain.

John C. Webster, M.D., Lafayette, Ind.; Rush Medical College, 1870; aged 76; a Fellow of the American Medical Association; formerly president of the Indiana State Board of Medical Registration and Examination; consulting physician to St. Elizabeth's Hospital, Lafayette; died, November 11, from the effects of carbolic acid accidentally self-administered, in mistake for liquid petrolatum.

Jefferson A. Davis, M.D., Kansas City, Kan.; Medico-Chirurgical College of Kansas City, Mo., 1902; aged 54; a Fellow of the American Medical Association; for eight years coroner of Wyandotte County, Kan., and formerly police surgeon of Kansas City, Kan.; died in St. Margaret's Hospital, Kansas City, Mo., October 7, from heart disease.

Andrew Jackson Hall, M.D., Natchez, Miss.; Bellevue Hospital Medical College, 1879; aged 78; formerly a Fellow of the American Medical Association; vice president of the Mississippi State Medical Association in 1892; a member of the staff of the Natchez City Hospital since 1889; a Confederate veteran; died in New Orleans, October 21.

Horace Edward Bunce, Jr., M.D., Pittsburgh; Western Pennsylvania Medical College, Pittsburgh, 1900; aged 47; formerly a member of the Medical Society of the State of Pennsylvania; a member of the medical staff of the Jones and Laughlin Mills, Pittsburgh; died at his home, October 28, from septicemia.

George L. Saunders, M.D., Columbus, Ohio; Ohio State University, Columbus, 1908; aged 43; a member of the Ohio State Medical Association; formerly a member of the staff of the Ohio Hospital for Epileptics, Gallipolis; died in Grant Hospital, Columbus, October 29, from disease of the intestine.

John Milton Dexter, M.D., New York City; College of Physicians and Surgeons in the City of New York, 1894; aged 49; formerly a member of the Medical Society of the State of New York; was run over and killed by an automobile, near his home, November 1.

Albert Nathan, M.D., Charleston, S. C.; Medical College of the State of South Carolina, Charleston, 1909; aged 31; a member and once secretary of the South Carolina Medical Association; died in Boston, October 22.

Paul S. Morrison, M.D., Bancroft, Kan.; Ensworth Medical College, St. Joseph, 1909; aged 33; for several years a druggist and physician of South St. Joseph, Mo.; died in a hospital in Atchison, Kan., November 2.

A. C. McNutt, M.D., Bucyrus, Ohio; Starling Medical College, Columbus, Ohio, 1856; aged 89; surgeon of the Eleventh Ohio Volunteer Infantry during the Civil War; died at his home, October 16, from uremia.

Abraham L. Lehman, M.D., Philadelphia; Medico-Chirurgical College of Philadelphia, 1899; aged 62; a pioneer of the Coeur d'Alène district; died in the Providence Hospital, Wallace, Idaho, October 21.

William Albert McCallie, M.D., Knoxville, Tenn.; Vanderbilt University, Nashville, Tenn., 1876; aged 65; formerly a member of the Tennessee State Medical Association; died at his home, October 18.

James H. Dobbins, M.D., Bellefonte, Pa.; University of Pennsylvania, Philadelphia, 1849; aged 90; formerly a member of the Medical Society of the State of Pennsylvania; died at his home, recently.

Dennie Daniel Trotter, M.D., Madison, Ga.; Atlanta, Ga., School of Medicine, 1912; aged 28; formerly a member of the Medical Association of Georgia; died in a hospital in Atlanta, October 16.

Decatur H. Burk, M.D., Warner, Okla.; Medical College of Georgia, Augusta, 1889; aged 67; formerly a member of the Oklahoma State Medical Association; died in Muskogee, Okla., October 24.

John Kolmer, M.D., Indianapolis; Jefferson Medical College, 1894; aged 51; a Fellow of the American Medical Association; a well known surgeon of Indianapolis; died at his home, October 21

John Craig Johnstone, M.D., Lawton, Okla.; St. Louis University, 1912; aged 4; formerly a member of the Oklahoma State Medical Association; died in Blackwell, Okla., October 7, from diabetes.

James M. Bartholow, M.D., Urbana, Ill.; Rush Medical College, 1871; aged 70; a member of the Illinois State Medical Society; a veteran of the Civil War; died at Champaign, Ill., October 8.

James A. Summers, M.D., Johnson City, Tenn.; College of Physicians and Surgeons, Baltimore, 1874; aged 69; died at his home, August 4, from dysentery and laryngeal tuberculosis.

Rudolph Myers, M.D., Huntingdon, Pa.; Bellevue Hospital Medical School, 1863; aged 77; a Fellow of the American Medical Association; died at his home, August 24, from toxic myocarditis.

Edward Johnson, M.D., Columbus, Neb.; Medical School of Maine, Portland, 1883; president of the First National Bank of Columbus; died in the Clarkson Hospital, Omaha, October 27.

Newton C. Davis, M.D., Kingman, Kan.; Homeopathic Hospital College, Cleveland, 1884; aged 61; formerly a member of the Kansas Medical Society; died at his home, about October 25.

Samuel A. Orentreich, M.D., Denver; University of Krakow, Austria, 1890; died in Detroit, October 23, from the effect of poison, self-administered, it is believed, with suicidal intent.

Robert Lee Ray, M.D., Monterey, Tenn.; University of Tennessee, Nashville, 1892; aged 52; a Fellow of the American Medical Association; died in his office, October 29.

Isaac B. Gallup, M.D., Willimantic, Conn.; Philadelphia University of Medicine and Surgery, 1869; aged 72; died at his home, August 2, from carcinoma of the bladder.

Levi A. Horn, M.D., Austin, Pa.; University of Louisville, Ky., 1894; a member of the Medical Society of the State of Pennsylvania; died at his home, about August 15.

Samuel O. Knapp, M.D., Frankfort, Ind.; Medical College of Ohio, Cincinnati, 1884; aged 59; died in Mulberry, Ind., September 20, from chronic interstitial nephritis.

Charles Z. Ellis, M.D., Berkeley, Calif.; California Eclectic Medical College, Los Angeles, 1891; aged 54; died in Berkeley, October 16, from carcinoma of the stomach.

F. N. Sheppard, M.D., Riverside Manor, Md., American College of Medicine, Philadelphia, 1865; aged 78; died at his home, near Crumpton, Md., October 14.

Andrew N. Falkenstein, M.D., Glen Rock, Pa.; College of Physicians and Surgeons, Baltimore, 1887; aged 63; died at his home, October 19, from nephritis.

Henry T. Fullerton, M.D., Kenton, Tenn.; Missouri Medical College, St. Louis, 1866; aged 77; died at his home, September 4, from cerebral hemorrhage.

Charles C. Dalton, M.D., Wiota, Wis.; Bennett Medical College, Chicago, 1903; aged 39; died in Madison, Wis., September 15, from pneumonia.

Thomas C. Van Tries, M.D., Bellefonte, Pa.; University of Pennsylvania, Philadelphia, 1868; aged 38; died in Pittsburgh, August 1, from pneumonia.

John G. Rogers, M.D., Cherrygrove, Tenn.; Vanderbilt University, Nashville, Tenn., 1875; aged 78; died at his home, July 14, from nephritis.

Merriken B. Lukens, Atlanta, Ga. (license, Georgia); a practitioner since 1871; aged 83; died at the home of his niece in Atlanta, October 22.

John R. Bartlett, Burlison, Tenn. (license, Tennesse, 1889); aged 61; a practitioner since 1880; died at his home, July 28, from angina pectoris.

Joseph George Church, M.D., Shenandoah, Pa.; University of Pennsylvania, Philadelphia, 1887; aged 52; died at his home, October 19.

Jesse B. Mitchell, Sneedville, Tenn. (license, Tennessee, 1889); aged 76; died at his home, August 22, from cerebral hemorrhage.

Joseph James Harrison, M.D., Loudon, Tenn.; University of Nashville, Tenn., 1854; aged 83; died at his home, October 25.

Charles Dingee, M.D., Burlington, N. J.; University of Pennsylvania, Philadelphia, 1887; died at his home, October 10.

Joseph Lewandowski, M.D., Boston, Mass.; University of Krakow, Austria, 1894; aged 53; died at his home, October 23.

Oran A. Dean, M.D., South Haven, Mich.; University of Buffalo, 1868; died at his home, October 19.

The Propaganda for Reform

In This Department Appear Reports of the Council on Pharmacy and Chemistry and of the Association Laboratory, Together with Other Matter Tending to Aid Intelligent Prescribing and to Oppose Medical Fraud on the Public and on the Profession

IODEOL AND IODAGOL

Report of the Council on Pharmacy and Chemistry

Iodeol and Iodagol (formerly called Iodargol) are products of Viel and Company, Rennes, France, widely advertised in this country by David B. Levy, Incorporated, New York. The claim made for both preparations is that they depend on "colloidal iodin" for their action. They are put up in a number of forms, for instance:

"Iodeol Ampoules each containing 1 c.c. (20 centigrammes colloidal iodin in an oily vehicle)."

"Iodeol External, containing 50 per cent. colloidal iodine."

"Iodagol Ampoules, each containing 2 c.c. (50 centigrammes colloidal iodine in an oily vehicle)."

The claim is, that, the iodin being in the colloidal state, it has the properties of elementary iodin and thus the preparations may be used in concentrations and under conditions which would make the use of free iodin impossible. The products have been extensively and extravagantly advertised for use in a wide range of conditions. Thus Iodeol has been proposed in the treatment of:

"Pulmonary Tuberculosis"
"Laryngeal Tuberculosis,"
"Glandular Tuberculosis"
"Tuberculosis of the Bones"
"Pneumonia, Broncho-pneumonia, and Congestive Conditions"
"Whooping Cough, Influenza, Asthma"
"Typhoid Fever"
"Syphilis"
"Obesity".

Iodagol, which is for external use, has been advised in the treatment of:

"Gonorrhea and its Sequelæ"
"Cystitis"
"Tetanus"
"Wounds complicated by gaseous gangrene"
"Burns"
"Old Suppurations, ulcers, abscesses, etc."
"Articular rheumatism"
"Abscess Alveolar"
"Pyorrhea Alveolaris"
"Stomatitis (Canker-Sores)."

Nearly two years ago the American agents requested the Council to consider Iodeol and Iodagol for admission to New and Nonofficial Remedies. The information submitted in regard to their character and composition was vague and indefinite, the pharmacologic information practically nil and the clinical data as voluminous as it was unconvincing.

On the basis of chemical, pharmacologic, bacteriologic and clinical investigation carried out under the direction of the referee and a study of the submitted evidence, the referee reported:

1. Iodeol and Iodagol do not contain the amount of iodin claimed.
2. The iodin is not present as elementary iodin, but instead the preparations behave similarly to the well-known organic iodin compounds such as iodized fats.
3. The therapeutic claims made for the preparations are exaggerated and unwarranted.

In view of his findings he recommended that Iodeol and Iodagol be declared inadmissible to New and Nonofficial Remedies for conflict with Rules 1 and 2 (misleading statements regarding composition and identification) and Rule 6 (unwarranted therapeutic claims). The Council adopted the recommendation of the referee, directing inclusion of the full report in the annual Council reports after submission to the manufacturer, and recommending publication of an abstract of this report in The Journal.

This report was brought to the attention of the American agent, David B. Levy, Inc., and through them to the French manufacturers, E. Viel and Company. The manufacturers have intimated that they will not file a reply to the report. The firm of David B. Levy, Inc., has decided to sever its connection with these products and to discontinue their sale.

W. A. Puckner, Secretary.

Referee's Report

Iodeol and Iodagol were submitted to the Council nearly two years ago as "electro-colloidal iodine" and with the claim that they produced all the antiseptic and other effects of ordinary iodin without any of its side actions. The referee has done much work on the subject, conducted a large amount of correspondence and has contended with long delays. He feels that the consideration of these products should be brought to a conclusion and accordingly he submits this report of their consideration. The following is a summary of the report, which is appended:

I. Discrepancy in Iodin Percentage.—The examination at the Chemical Laboratory of the American Medical Association, as well as that of the referee, shows that the various samples of Iodeol and Iodagol examined contained a little less than one-half of the total iodin claimed. These facts were reported to the American agent. After a lengthy delay a reply was received which presented a double excuse: (1) that the full amount of iodin had been added, whatever had become of it later; (2) that the claims were made for "colloidal iodin" and that this is not elementary iodin in the colloidal state, but a preparation of iodin containing only 50 per cent. of real iodin. Neither explanation can be taken seriously, as they are obvious quibblings. The referee concludes that the preparations are falsely labeled as to iodin content.

II. Nature of the Iodin Compound in Iodeol and Iodagol.—In the information sent the Council, Iodeol and Iodagol were defined as "A suspension of electro-chemical colloidal iodin in a vehicle of purified oil." Numerous inquiries have failed to elicit more specific information from the manufacturer or his agent. The statement of composition can mean only that the preparations contain free iodin (but in colloidal form) suspended in oil. No evidence to substantiate this claim has been submitted. (There is evidence that the preparations contain colloidal particles, but it does not indicate if this colloidal material is iodin, or a combination of iodin or indeed whether the colloid component contains any iodin.) The recent statements of the agent seem to concede that what they call "electro-colloidal iodin" contains only about 50 per cent. of real iodin, in other words that it is not "colloidal iodin" at all but a mixture or combination of iodin with some other unnamed substance. This, of course, is something very different.

Certain results reported from the American Medical Association's Chemical Laboratory suggest that the so-called "colloidal iodin" of Iodeol may be a combination of iodin with a volatile oil. The investigations of the referee indicate that the iodin exists in a rather resistant form or combination behaving altogether differently from ordinary free iodin, and rather resembling the behavior of iodin substitution products, such as iodized fats or phenols. Briefly, then, the recent admissions of the agents indicate that Iodeol does not contain "colloidal iodin" in a chemical sense, and there are indications that it does contain its iodin in a rather firm (chemical) combination.

III. Chemical Properties of Iodeol.—From a study of different specimens of Iodeol, the referee concludes that fresh specimens contain no free iodin and that old ones contain small amounts as a result of decomposition. Iodeol has the solubility characteristics of fats and fat-like compounds. The examination, as a whole, shows that Iodeol contains a peculiar and rather resistant form or combination of iodin. There is nothing in the chemical data that suggests that it could act differently from ordinary iodin compounds, such as iodized fats. It would not act as ordinary iodin.

IV. Pharmacologic Data.—The pharmacologic statements which were submitted were loose and apparently meaningless or misleading. In reply to questions submitted by the referee, the manufacturer finally had some work done and submitted a report by Jean Laumonnier. The referee was unable to confirm some of this work, and as a whole it does not appear materially to elucidate the action of Iodeol. From a consideration of the submitted evidence and as a result of his own work, the referee concludes that Iodeol does not behave like elementary iodin; it does not coagulate proteins and therefore is not irritant. It is presumably absorbed, but quite probably after chemical change; it is changed into iodid and, like organic iodids, is excreted somewhat more slowly than when inorganic iodids are administered, but the difference does not appear important.

V. Antiseptic and Bactericidal Action.—Elementary iodin is considered a fairly powerful agent in these respects. The activity is presumably due to changes in the proteins, etc., of the bacteria, analogous to the effects which produce pain, irritation and necrosis of the tissue cells. Since the latter effect is not produced by Iodeol, it seems highly improbable, if not impossible, that it should act on bacteria like elementary iodin. It is entirely unjustifiable to credit the known antibacterial qualities of ordinary iodin to "colloid" iodin. This misrepresentation is especially prominent in the circular "Notable New Therapeutic Agents," as will be seen, for instance, from the following citations:

> "Iodine has long been universally recognized as an antiseptic of extraordinary potency. Not only is it *rapid* and certain in its germ-destroying action, but it *also* possesses an attribute denied many other antiseptic agents, *namely*, the *power* to penetrate and *impregnate* the tissues. Other antiseptics, as is well known, act on the surface epithelium only."
>
> "According to Kinnaman (JOURNAL A. M. A., Aug. 26, 1905), iodine is far superior to bichloride of *mercury*, a two per cent. solution killing streptococcus pyogenes in two minutes. Iodine does *not* coagulate *albumin*, and is very penetrating."

The citations imply that this "colloidal iodin" of Iodeol and Iodagol acts as an antiseptic like ordinary iodin, except that it is claimed to be more efficient by "diffusing" more readily. This is entirely unjustified and misleading. If Iodeol and Iodagol are really antiseptic, they must act by some other mechanism than that through which elementary iodin acts, and such antiseptic action would have to be demonstrated by direct observation and not assumed from the known action of free iodin.

Antiseptic and bactericidal effects are easily estimated by laboratory methods. Yet no evidence on this point appeared to have been available until the Council called for this. Laumonnier then carried out some experiments which were in turn submitted to bacteriologic control. The bacteriologist failed to obtain any results with some of the tests, and considered the other data of little value.

The claim that Iodeol and Iodagol have the antiseptic and bactericidal action of free iodin lacks proof and must be considered unwarranted and misleading in the extreme.

VI. Clinical Trials.—The manufacturers and agents of Iodeol presented many letters from physicians; but few, if any, of these gave evidence of careful, critical, controlled observations. They could not, therefore, be considered as acceptable evidence. The more important claims, letters and published papers, however, were submitted to clinical specialists collaborating with the Council, with the request that they examine these and conduct some clinical trials, if they considered it advisable. The results obtained in these preliminary trials did not appear sufficient to warrant further experimentation.

From a consideration of the evidence presented, the referee concludes that the claims made for Iodeol and Iodagol are unwarranted, exaggerated and misleading. He recommends that Iodeol and Iodagol be declared ineligible for New and Nonofficial Remedies for conflict with Rules 1 and 2 (misleading statements as to composition and identification) and with Rule 6 (unwarranted and misleading therapeutic claims). He further recommends that the Council authorize publication of the preceding summary of the consideration of Iodeol and Iodagol in THE JOURNAL and inclusion of the full report in the annual Council reports after submission to the manufacturer.

Garbage Saving at Army Cantonments.—Another practical demonstration of what may be done in the use of garbage is made by the War Department in the Army training camps. The garbage of thirteen of the cantonments will be sold to a contractor for feeding swine, yielding the government an annual price of $446,394. It is estimated that garbage waste from ten to fifteen soldiers will feed one hog, putting onto the animal 1 pound of weight per day. At this rate garbage from thirteen cantonments will produce 18,900,000 pounds of pork yearly. In cases where garbage can not be used for feeding, it will be treated for grease extraction and the tankage ground for stock food or fertilizer. The custom of burning garbage will be abolished altogether. The War Department will receive $240,000 annually for the manure from the horses and mules at Army cantonments.—*Weekly Bulletin.*

"DISORDERED ACTION OF THE HEART" IN BRITISH SOLDIERS

To the Editor:—The report on soldiers returned as cases of "disordered action of the heart" of the Medical Research Committee in England has recently been supplemented by reports of the detailed clinical studies made by members of the staff, contained in *Heart*, **6**, No. 4. The most striking features of these excellent and very detailed studies are, first, the negative conclusions as to the etiology and pathology of this syndrome, and, second, the positive conclusion that graduated exercises cure a large proportion of the patients.

These patients show certain symptoms which to my mind are most significant—breathlessness, and blood pressure and pulse reactions to exercise. The authors state that "the response of the respiratory rate to exercise is a very exaggerated one." Again, "None of our patients are capable of such effort (i. e., amounts of work healthy young adults are capable of) : equal distress and similar pulse rates and systolic pressure are produced by smaller amounts of work or work done more slowly. It is clear that if we chose a given amount of work as a stimulus and apply the stimulus to healthy controls and to our patients, the latter react to the stimulus in an exaggerated fashion. The pulse rate rises much higher than in controls, and the high rate is longer sustained, the blood pressure rises higher, and the raised pressure is longer sustained than in controls: the summit of the blood pressure is not delayed,[1] however: breathlessness, fatigue and palpitation are also much more in evidence."

It seems to me very clear that the patients who presented the foregoing symptoms were suffering from a decreased cardiac reserve power. The fact that so many of them were cured by graduated exercises affords additional and convincing proof. The neurotic symytoms that were often present are not necessarily a sequence of the decreased cardiac reserve power, but probably are simply a concomitant. Very possibly they are caused by the same factors that produced the decrease in cardiac reserve power.

We frequently see these patients with decreased cardiac reserve power in civil life, and graduated exercises cure them. One half of the patients described in the report dated the onset of symptoms a number of years back. Infections of various kinds contracted during service immediately preceded the onset of symptoms in another large group. The cardiac reserve power is always lowered after any infection of moderate severity. Any one who has indulged in exercise too soon after a sojourn in bed with fever can appreciate the truth of this statement. The report takes cognizance of this etiologic factor when it states that "convalescent treatment should be more prolonged than is often the case; a graduated system of retraining seems most desirable."

A group of patients is described who suffered from precordial pain and in many instances hyperesthesia of the chest wall, both accentuated by exercise. The circulatory reactions of this group to exercise are not given except in one instance, probably because it was inadvisable to carry out exercise experiments on account of their effect on the pain. These patients are quite rare in civil life, and their subsequent histories would be of much value.

Objections may be made to my use of the term "cardiac reserve power." The heart's total capacity is made up of two component parts; one, the smaller, comprises the power expended in furnishing the requirements of the metabolism with the body at rest; the other, by far the larger, is utilized when physical work is performed. It is this potentially large component that is called into action by graduated exercises. Any expression which describes a definite function of a bodily organ has a perfectly legitimate use. In this instance the term "cardiac reserve power" denotes a most important function of the heart, the variations of which are matters of personal experience to every man who has gone through a course of physical training. Our inability to measure the heart's reserve power directly is not a reason for ignoring its existence.

---

[1] The summit was not delayed because the authors in each experiment stopped increasing the work just as they were about to reach a "delayed rise." The controls were given from ⅓ to 4 times more work than the patients (comparing the maximum amounts given). Had the authors been a little more persistent they would have found the "summit of maximal pressure is delayed" exactly as they found it was in normal patients and with decidedly less work.

When the reserve power is impaired, not from organic disease of the heart, but from any one of numerous causes, there is presented a characteristic clinical picture which to my mind the authors of this report have described quite accurately. The neurotic symptoms from which these patients suffer do not alter the significance of the respiratory and circulatory reactions to work or the significance of the curative effect of graduated exercises.

Theodore B. Barringer, Jr., M.D., New York.

THE CARREL-DAKIN TREATMENT

To the Editor:—I am enclosing a letter which I wrote recently to Dr. William H. Welch in regard to the Carrel method of wound treatment which is at present so actively under discussion. I believe that it presents a point of view that might very well be presented to the profession at this time through the columns of The Journal.

Arthur Dean Bevan, M.D., Chicago.

My Dear Dr. Welch:

I want to write you about a problem which I think is of considerable importance to the Medical Corps at this time and in which I believe you are interested. The problem is that of the Carrel method of wound treatment. I of course have followed in the past two years the surgical literature on this subject with a great deal of interest. At the meeting of the American Surgical Association this spring, Dr. Charles Gibson of New York read a paper on this subject, and at the American Medical Association meeting in June, Dr. William Sherman of Pittsburgh discussed the subject before the surgical section. They both presented the subject in a most enthusiastic way and made very startling claims for the new method. These were so out of keeping with the reports that I have been able to obtain from well qualified surgeons of large experience who had the opportunity of employing it in their military hospital work, and were in such opposition to the generally accepted views of surgical pathology and wound repair, that I have taken the pains to go into the subject pretty fully with an attempt to analyze the facts and arrive at a judicial opinion as to its value.

When I was in Washington during the first two weeks in October, I found that classes of men were being sent to the Carrel Hospital in connection with the Rockefeller Institute in New York for the purpose of taking short courses in the Carrel-Dakin method. On leaving Washington I went to New York and spent one morning at the Carrel Institute and had the opportunity of obtaining a syllabus of the work that is being done in these courses, of seeing their hospital and laboratories, and of witnessing one operation done by Josh Hartwell, not under the supervision of Carrel himself, but of a French army officer who is at the hospital and who has been with Carrel for some time.

I found in discussing personally with several surgeons and from letters and reports which I have had an opportunity of reading from Dr. James Neff, who was in charge of a base hospital of a thousand beds or more for a year on the western front, from a report by Dr. George Crile, from a talk with Dr. James Burry, who has had the treatment tried for a number of months in his accident work in the Illinois Steel Company, from the statements made by Fred Murphy and reports from Joe Blake, and personal communication from Sir Berkeley Moynihan, that they and many surgeons were skeptical as to its practical value. I did not venture, however, to form an opinion of my own until I had the opportunity during the last week of reading Carrel's book and analyzing the problem from this report of his own work. I should like to make clear that the views that I express in this letter are not obtained from any hearsay evidence but from an analysis of Carrel's own views expressed in this book. One of the important parts of modern surgery and one of the things that has made modern surgery possible is that division of the science that is known as surgical pathology. By this I mean a division of pathology that has been specially studied and developed by scientific clinical surgeons. It is only necessary for me to state that the development of modern surgical pathology rests on the work of Lister, of Paget, of Billroth, of such men in this country as Fenger and Senn, and is well presented today by the work done by Lexer and presented in a book which is known as Lexer's "General Surgery." From the time of Lister until now, scientific clinical surgeons have studied the special pathologic problems that were involved in the science and practice of surgery. The problems of wound repair, of infection and the processes by which an organism frees itself from infection, separating the living from the devitalized tissues, the extrusion, digestion and encapsulation of foreign bodies, etc., have been studied with the greatest possible care, and many of these problems worked out as thoroughly both experimentally and clinically as in any field of medical science. Analyzing the Carrel work from the standpoint of what is known of modern scientific surgical pathology, I am forced to the conclusion that his work does not at all meet the requirements essential to a piece of scientific research. I take it for granted that the chemical problems involved have been scientifically handled; but the problems of surgical pathology have been handled in a superficial, incomplete way without the necessary controls, and frankly the conclusion is forced on me that Carrel's part of the work is not scientifically proved and cannot be accepted.

It is evident as one analyzes Carrel's statements that it is a piece of work done by a laboratory man who does not understand the clinical problems involved, who either does not know or ignores many essential facts, and whose conclusions as to the miracle working effects of the Dakin solution in his scheme of treatment have about as little basis in fact as the exaggerated claims that have been made for "ambrine" in the treatment of burns. The trouble is that this problem has not been attacked in the right way. A problem of this kind should be attacked by the joint labor of a number of teams, each one composed of a thoroughly scientific clinical surgeon who is well trained in the science of surgical pathology, in conjunction possibly with such a laboratory worker as Carrel, and with the assistance of competent chemists and bacteriologists. It should be attacked in the most scientific and broadest possible way and with the necessary controls, controls that would enable the investigators to determine, first, the results from the employment of the accepted surgical methods of surgical technic as applied, for instance, to a shell wound of the thigh with compound fracture of the femur, including the earliest possible removal of foreign bodies and of devitalized tissue, the complete excision of the wounds with immediate closure in some cases and with free drainage, moist dressing with sterile water in others, the immobilization of the limb and the best possible general care of the patient, and the results of such wound treatment which could be designated as the control compared with similar cases treated with the employment of various antiseptic solutions, including the Dakin fluid. These experiments to be of value would have to be on a considerable scale. I am personally so thoroughly convinced that wound healing and the freeing of tissues and an organism from infection depends so largely on the life processes in the living cells at the point of injury and infection and the reaction of the sum total of living cells that make up the entire individual, and that the important thing that a surgeon can do is to eliminate noxious influences and place the particular part injured and the entire individual in a condition where this wound repair and elimination of infection can go on uninterfered with as little as possible, that I can see but a limited value in the local employment of antiseptics of any kind on the surface of the infected wound. That any antiseptic has any healing property, that any antiseptic is miracle working in the handling of wounds, is inconceivable.

Looking at the problem in a broad way, if we could express in figures the value of the means at our disposal of treatment of the shell and rifle wounds of this war, certainly much more than 90 per cent. of the sum total of the value of wound treatment would consist of the proper employment of the well known and generally accepted rules of surgical technic. Granted that the remaining 5 or 10 per cent. depended on the proper employment of antiseptic solutions, one may be very sure that the choice of one of a half dozen thoroughly tried out antiseptics, such as boric acid, aluminum acetate, Dakin solution, dichloramin-T, hydrogen peroxid, phenol and iodin, would not make any enormous difference in the sum total of the end-results.

If the above statements are true, it would be a serious mistake for the government medical services to adopt the Carrel treatment as a great and wonder-working improvement in our surgical technic, and to force a complicated, time-consuming, expensive plan of treatment on our medical service, possibly to find within a short time that it is of little or no value. As I have studied Carrel's book and attempted to form a judicial opinion of this problem, I am forced to the conclusion that, like Koch's lymph, Bier's hyperemia and the vaccine therapy for acute infections, the Carrel treatment will have a short period of popularity among that small corps of enthusiasts of the type that is easily carried away by new, startling methods, and like the Bier's hyperemia and the vaccine therapy for acute infections, will hortly disappear, consumed in the fire of actual experience and scientific research.

I am venturing to write this to you because I know how much you are interested in the sound, practical, successful organization of the Medical Department for this war, and because I know how deeply interested you are in the success of the Rockefeller Institute. I think this matter should be handled in a practical way in our army organization. The Carrel treatment cannot and should not be accepted at this time as a demonstrated truth. It should be accepted as a method that is experimental and under trial. It should not be adopted by the United States medical service to the exclusion of other methods. If possible, a number of base hospitals officered by strong corps of men should try out thoroughly, in a scientific way, the various methods of wound treatment that seem to offer possibilities of adding to our present knowledge in this particular field of surgical pathology. The very exaggerated claims which have gotten into our medical journals and even into the lay press should be disparaged by those who are in a position to control the situation.

Very truly yours,

Arthur Dean Bevan.

VARIATIONS IN RESISTANCE OF BLOOD CELLS TO HEMOLYSIS

To the Editor:—In conducting experiments with preserved complement, I have found that the complement apparently varies in strength from week to week, fluctuating from strong to weak and strong again, sometimes stronger the third week than the first.

I have found this to be due to a factor, hitherto unnoted, namely, the marked variation in resistance of different batches of blood cells to hemolysis. I want, therefore, to issue this note of warning to all serologists utilizing my complement preservative (The Journal, Sept. 22, 1917, p. 973): *It is necessary to retitrate the complement with each new supply of blood cells.* For example, one batch of blood cells required 0.175 of complement to complete the hemolytic system. Another batch of cells, used two days later, required only 0.1. Still another batch of cells, used two days following the latter, required 0.125 of this same complement for the Wassermann tests.

B. W. Rhamy, M.D., Fort Wayne, Ind.

BELGIAN AND FRENCH PHYSICIANS' FUND

To the Editor:—I beg leave to report the following contributions which have been made for the relief of the Belgian and French civilian physicians to enable them to reestablish themselves in their looted or even destroyed offices now made accessible by the retreat of the German army. This is in addition to the sum of $920 reported in The Journal, October 13. The total, including interest on the deposits, is $1,127.28. One half of this, $563.64, I have forwarded to Dr. A. Depage at La Panne, Belgium, through the Belgian Relief Committee, 1524 Walnut Street, Philadelphia. The other half I have forwarded to M. Charles Halais, 15 boulevard de Latour-Maubourg, Paris, for the French civilian doctors, through Mrs. Sara Y. Stevenson of the French relief here, 1122 Walnut Street.

I have also received instruments from the doctors named and also 5,000 disinfected fiber spoons from the Sanispoon Sales Co., Philadelphia. These disinfected and cheap spoons will be valuable to the civilian doctors in the cases of various contagious diseases, and they are so cheap that they can be used and thrown away.

I have to thank Charles Lentz & Sons, Philadelphia, for their very generous help in repairing and packing all the instruments. The value of the box sent to Belgium they place at $500. The box for the French doctors is not yet ready for packing.

Since this list has been made up and the checks sent several more contributions in money and instruments have been received. These will be acknowleged later. I hope for much more in money and in instruments.

Our colleagues when they return to their desolated and looted offices will bless their American colleagues for this timely help. Suppose the tables were turned and *we* were the sufferers. How grateful we should be!

W. W. Keen, M.D., Philadelphia.

TYPHOID IN THE WAR OF 1898

To the Editor:—1. How many cases of typhoid were there in the Army during the Spanish-American War? How many deaths from this disease?

2. To what degree is typhoid vaccine a preventive?

J. E. Brinkman, M.D., Waterloo, Iowa.

Answer.—1. In our war with Spain there were 20,738 cases of typhoid fever among 108,000 men, all occurring within three and one-half months. Typhoid fever caused nine tenths of all deaths among troops in the United States in 1898.

2. Antityphoid vaccination has demonstrated itself to be an almost certain preventive of typhoid fever. For comparison with the foregoing figures, on October 19, there were practically 1,000,000 soldiers in camp in the United States, all of whom had been vaccinated or were undergoing vaccination against typhoid fever, with a total incidence of twelve cases of this disease.

Medical Education and State Boards of Registration

COMING EXAMINATIONS

Delaware: Wilmington, Dec. 11-13. Sec., Dr. H. W. Briggs, 1026 Jackson St., Wilmington.

Florida: Jacksonville, Dec. 4-5. Sec., Dr. W. M. Rowlett, Citizens Bank Bldg., Tampa.

Kentucky: Louisville, Dec. 4-6. Sec., Dr. A. T. McCormack, Bowling Green.

Louisiana: New Orleans, Dec. 6-8. Sec., Dr. E. W. Mahler, 730 Audubon Bldg., New Orleans.

Maryland: Baltimore, Dec. 11. Sec., Dr. J. McP. Scott, 137 W. Washington St., Hagerstown.

Minnesota: St. Paul, Jan. 2-4. Sec., Dr. Thomas McDavitt, 741 Lowry Bldg., St. Paul.

Missouri: St. Louis, Dec. 17-19. Sec., Dr. George H. Jones, 206 Washington St., Jefferson City.

National Board of Medical Examiners: New York City, Jan. 9-17. Assistant Sec., Mrs. Isabelle F. Tiers, 310 Real Estate Bldg., Broad and Chestnut Sts., Philadelphia.

New Hampshire: Concord, Dec. 10-12. Sec., Dr. W. S. Crosby, Beacon Bldg., Manchester.

North Dakota: Grand Forks, Jan. 1. Sec., Dr. G. M. Williamson, Grand Forks.

Ohio: Columbus, Dec. 4-6. Sec. Pro-tem., Dr. Herbert M. Platter, 185 E. State St., Columbus.

Oregon: Portland, Jan. 1. Sec., Dr. Herbert S. Nichols, Portland.

Rhode Island: Providence, Jan. 3. Sec., Dr. B. U. Richards, State House, Providence.

Texas: Dallas, Nov. 20-22. Sec., Dr. M. F. Bettencourt, Mart.

Virginia: Richmond, Dec. 11-14. Sec., Dr. J. W. Preston, McBain Bldg., Roanoke.

Washington: Spokane, Jan. 1. Sec., Dr. C. N. Suttner, Baker Bldg., Walla Walla.

West Virginia: Clarksburg, Nov. 21-23. Chairman, Dr. S. L. Jepson, Capitol Bldg., Charleston.

California April Examination

Dr. C. B. Pinkham, secretary of the Board of Medical Examiners of the State of California, reports the written examination held at Los Angeles, April 9-13, 1917. The examination covered 9 subjects and included 90 questions. An average of 75 per cent. was required to pass. Of the 56 candidates examined, 40, including 27 osteopaths, passed, and 16, including 12 osteopaths, failed. Sixty-two candidates were licensed through reciprocity. Twelve candidates were granted drugless practitioner certificates. The following colleges were represented:

PASSED

College	Year Grad.	Per Cent.
College of Physicians and Surgeons of San Francisco	(1915)	85.7
Hahnemann Medical College of the Pacific	(1916)	75.5

Poliomyelitis in All Its Aspects. By John Ruhräh, M.D., Professor of Pediatrics in the University of Maryland Medical School and the College of Physicians and Surgeons, and Erwin E. Mayer, M.D., First Lieutenant in the Medical Reserve Corps, United States Army. Cloth. Price, $3.25. Pp. 297, with 120 illustrations. Philadelphia: Lea & Febiger, 1917.

The great epidemic of poliomyelitis of 1916 in New York and in the East generally has been productive of several books concerning this disease. This book contains an excellent historical review of the subject, illustrated with reproductions from some of the first monographs on the subject. The section on pathology follows the usual lines. Especial interest attaches to the discussion of the nature of the virus, a question now the subject of rather interesting argument. The authors consider literature up to July, 1917, and finally conclude that it is reasonably safe to state that the streptococci and diplococci found by various investigators are not the causal agents of the disease. The discussion of epidemiology and classification of the various types is excellent. The chapter on paralysis is illustrated with photographs of the different types of paralysis. A chapter is devoted, very properly, to the technic of lumbar puncture, a much needed lesson. Other chapters concern the diagnosis and prognosis. By far the larger portion of the book is devoted to treatment, which adds to the practical value of the work. The authors have very thoroughly covered most of the articles on treatment that appeared in periodical literature during the recent epidemic. The exceedingly valuable work of Lovett, leading to muscle training and exercises, is outlined in detail. The book concludes with a chapter of anatomic and physiologic reminders, and a complete list of all the epidemics from which the world has suffered. It is an excellent book, not only for those especially interested in poliomyelitis, but also for any physician who wishes to be thoroughly informed on this important disease.

Obstetrics for Nurses. By Charles B. Reed, M.D., Obstetrician to Wesley Memorial Hospital, Chicago. Cloth. Price, $2.50. Pp. 374, with 130 illustrations. St. Louis: C. V. Mosby Company, 1917.

The author has prepared a practical and complete manual of obstetrics for nurses. The subject is taken up in the usual order, a small amount of space being devoted to anatomy and physiology, followed by a discussion of normal and abnormal pregnancy, labor and puerperium; operations; complications; infection; a large section on the care of the child and infant feeding; an extensive list of diets and formulas; solutions; a therapeutic index, and a glossary. The book is well illustrated. It is interesting to find that the author recommends morphin and scopolamin for the first stage of labor, and gas for the second stage, with a change to chloroform and ether just before the completion of the second stage. The section on the care of the child is hardly up to the standard of the first part of the book. The author recommends a mixture of asafetida or whisky and hot water for attacks of colic. The therapeutic index might better have been omitted, especially since the pharmacology of several of the drugs hardly agrees with modern ideas, including the fact that at least three proprietary preparations are mentioned for which pharmacopeial preparations might better have been substituted. The increase in the cost of paper may be responsible for the fact that at least three different qualities of paper are used in the book. All in all, the book is to be recommended as a manual for the obstetric nurse.

Sanitation Practically Applied. By Harold Bacon Wood, M.D., Dr.P.H., Assistant Commissioner, West Virginia State Department of Health. Cloth. Price, $3 net. Pp. 473, with illustrations. New York: John Wiley & Sons, 1917.

This was written, the author states, as a practical guide for the field practice of sanitation. Omitting most of the details of analysis and examination from the laboratory side, which can be found in the larger treatises on hygiene and preventive medicine, the author covers a large field in such a manner that not only the physician and public health officer but also the layman will profit by reading the book. The opening chapter states the need for public health work, and maps the organization of a health department. In his discussion of the laboratory, it is interesting to note that Dr. Wood believes laboratory examinations for syphilis and gonococcal infections not made to determine quarantine are not the work for the public health laboratory. Statistics are reviewed in the second chapter. The third chapter reviews the latest methods of control of each of the communicable diseases. In considering Behring vaccination in diphtheria, a brief description of the methods would make the discussion clearer to the average reader. The author in successive chapters discusses child welfare, school hygiene, and the inspection and preservation of foods, giving a separate chapter to milk. Under water supplies are described the various modes of protecting and purifying water. Sewage disposal describes the care of sewage from the house to its final disposition, comparing the different methods of treatment. Industrial and occupational diseases are treated under hygiene of the home and factory. With our present knowledge of the rôle played by lower forms of animal life in transmitting disease, the chapter on the destruction of insects that transmit disease is especially timely. Methods also for destroying ground squirrels and our most deadly and expensive pest, the rat, are described. The last chapter is of particular interest to public health officers in that it outlines courses for interesting and teaching the people their part in conserving the health of the community.

An Index of Differential Diagnosis of Main Symptoms. By Various Writers. Edited by Herbert French, M.A., M.D., F.R.C.P., Physician, Pathologist and Lecturer, Guy's Hospital. Second Edition. Cloth. Price, $10 net. Pp. 912, with 343 illustrations. New York: William Wood & Co., 1917.

This book, which covers medicine in all its branches, is the combined work of twenty-three well-known English physicians and surgeons. The symptoms are arranged in alphabetical order, the symptom being named and followed by a discussion as to the possible diagnosis in the presence of the symptom discussed. Because of its size, it is impossible to review all of the various sections of the book critically. It is well printed on enameled paper of excellent quality. There are 306 good halftone illustrations and thirty-seven colored plates. The final 150 pages are devoted to an index in which main topics are distinguished from notes and mere mention of the subjects discussed. This index in itself is a thought producer; for example, a reference to the main heading is followed by an outline of the possible diagnosis attached to this symptom.

Congenital Word-Blindness. By James Hinshelwood, M.A., M.D., F.R.F.P.S., Lecturer on Ophthalmology in the Glasgow Western Medical School. Cloth. Price, 4 shillings net. Pp. 112. London: H. K. Lewis & Co., Ltd., 1917.

This is not only a valuable and convenient monograph for those interested in the subject, but so far as we know the only collective work in this restricted field. First, the author gives an excellent description, with illustrative cases, of acquired word-blindness. A brief history of our knowledge of this particular defect as a congenital condition and a statement of the symptomatology follow. Cases are then reported. Finally there is an account of the syndrome as a family or hereditary occurrence, and a consideration of prognosis and treatment. The book should be on the shelves of every neurologist and pediatrician, and the principal features of the syndrome in a compartment of his memory.

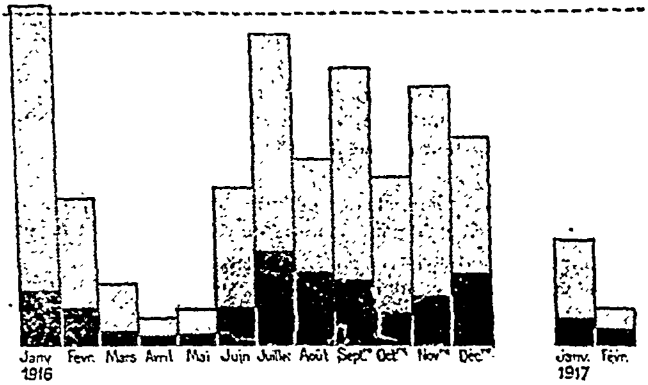
Bibliography of Titles on Poliomyelitis Contained in the Supplementary Card Catalogue of the Library of the Surgeon-General's Office. 1908-1917. Compiled by the Medical Department of the American Research Institute (May 15, 1917). Paper. Price, $5. Pp. 80. Washington: American Research Institute, 1917.

This bibliography supplements the references in Volume 13 of the Index Catalogue of the Library of the Surgeon-General's Office published in 1908. It contains approximately 1,500 titles of books and articles, and in the arrangement of the articles and in the citation of the references the general style of the Index Catalogue is followed. The American Research Institute will issue quarterly a supplement to this bibliography at $1 for every 500 titles.

Social Medicine, Medical Economics and Miscellany

Share of Vaccination Against Typhoid and Paratyphoid in the Disappearance of These Diseases in the Macedonian Campaign

P. Armand-Delille, Paisseau and Lemaire call attention to the success of the vaccinations in reducing typhoid and paratyphoid among the troops in the Saloniki region, the *armée d'Orient,* as they call it. They emphasize first the almost exclusive limitation of the cases of typhoid to the nonvaccinated, and, secondly, the almost complete disappearance of paratyphoid after the vaccine included both the paratyphoid A and B bacilli as well as the typhoid. Their figures include the entire Saloniki region and show the proportion per thousand men. The large number of cases in the summer months was due to the fatigues of the occupation of Macedonia and an extensive offensive. The mixed vaccine was not obtained until June, and was not generally used until toward the close of 1916. The effects are shown best by comparing the records for January, 1916 and 1917, although the troops at the later date were undergoing greater hardships than the year before. The total number of cases of typhoid, January, 1916, was 0.20 per thousand men, and of paratyphoid, 0.85. In January, 1917, the proportions were 0.09 typhoid and 0.22 paratyphoid, while in February the figures were respectively 0.05 and 0.06 per thousand men.



Typhoid and paratyphoid after combined vaccination.

Report of Rockefeller Foundation

The annual report of the Rockefeller Foundation for 1916 covers three of the chief activities of the foundation: the work of the International Health Board, the China Medical Board and the War Relief Commission. The International Health Board during the period named began work in Siam, Ceylon, Salvador and Brazil in cooperation with the governments of those countries for the relief and control of hookworm disease. This work also included activities in eight of the Southern States and fifteen foreign countries, and arrangements have been made to begin similar work in the Fiji Islands, Queensland and elsewhere. The report also includes the work of the Yellow Fever Commission headed by Surgeon-General Gorgas, which made a survey of the yellow fever situation in South and Central America. This commission found that Guayaquil, Ecuador, was the chief focus of the spread of yellow fever, with certain portions of the Carribbean Coast of South American and Eastern Brazil as points to be carefully watched. Intensive experiments were carried out in circumscribed areas in the Southern States, looking to the control of malaria. Three of these experiments were completed in 1916 with promising results, showing the feasibility of malarial control.

The China Medical Board, to promote the development of a comprehensive and efficient system of medicine in China, in addition to appropriations to existing medical schools and missionary organizations throughout China, voted to establish a medical school in Shanghai; a premedical school in Pekin for the preliminary education of students who are to take up the medical course, it being found that the scientific courses in existing Chinese schools are not sufficiently advanced to prepare students for the medical courses, and a Red Cross hospital in Shanghai. The services of Dr. Henry S. Houghton, formerly dean of the Harvard Medical School of China, were arranged for from July 1, 1916. He is to have charge of the Red Cross hospital, and will cooperate with Mr. Greene in directing the board's activities in China.

The foundation and the General Education Board have pledged a million dollars each toward the development of a center of medical education in connection with the University of Chicago; also in cooperation with the authorities of Johns Hopkins University an appropriation of $267,000 was made to establish in that university a school of hygiene and public health, which opened in October, 1917, with Dr. William H. Welsh as director. This school is intended to fit men for a public health career.

Medicolegal

Trained Nurses as Anesthetists, and the Practice of Medicine

(Frank et al. vs. South et al., State Board of Health (Ky.), 194 S. W. R. 375)

The Court of Appeals of Kentucky reverses a judgment that was rendered in favor of the plaintiff members of the state board of health, the court being of the opinion that defendant Hatfield, a trained and licensed nurse, in the performance of services as an anesthetist for defendant Frank, a duly licensed physician and surgeon who limited his practice to surgery, was not engaged in the practice of medicine, within the meaning of the statute laws on that subject.

The court says it has never heretofore been called on to define the term "the practice of medicine" as defined in the present statute, or to determine what things were or were not within the meaning of that act. While the practice of medicine is one of the most noble and learned professions, it is apparent that such a construction ought not to be given to the statute which regulates the profession that the effect of it would be to invade the province of the professions of pharmacy, dentistry or trained nursing, all of which are professions which relate to the alleviation of the human family of sickness and bodily afflictions, and to make duties belonging to those professions also "the practice of medicine" within the meaning of the statute. Neither should such a construction be given to it as to deprive the people from all service, which could be rendered to them in sickness and affliction, except gratuitous service, or else by licensed physicians, unless the legislature intended that such should be the result of the enactment of the statute.

As used in the present statute, the words "treatment of any human ailment or infirmity by any method" mean only to undertake the cure of any ailment or infirmity by some method, and it is clear that the legislative authority so understood it when it enacted the statute. To say that the term "practice of medicine" means the "treatment of any human ailment or infirmity by any method" is only an equivalent to saying that the practice of medicine shall be construed to be the attempt to effect the cure of such ailment by the application of some method, without regard to the method used. To do this it is necessary that the one undertaking the practice of medicine or to treat any human ailment or infirmity for the purpose of effecting a cure or to alleviate suffering arising from it by a method other than a treatment by medical agencies must necessarily do the things which are necessary to be done by one undertaking to practice medicine by medical agencies alone, and that is, he must make such a diagnosis of the symptoms of the ailment to determine what the ailment is. He must furthermore determine what the remedy should be and how it should be administered and when it should be administered, and then to administer the remedy, either in person or by directions to some one who is associated with the patient. It was contended that the language "the treatment of any human ailment or infirmity by any method" was enlarged by the language preceding it: "To treat the sick or injured or in any way discharge the duties usually performed by physicians, whether by medical, surgical or mechanical means"; but, construing all of the language of the subsection together, it is evident that "or in any way discharge the duties usually performed by physicians" must necessarily mean the duties usually performed by physicians in the practice of medicine at the time of the enactment of the statute and as understood at that time. The things usually performed by physicians which are not the practice of medicine are not included or intended to be included in the act.

It is the duty of the surgeon who would undertake a surgical operation to make a diagnosis of the symptoms of the patient to determine his ailment and the remedy necessary, and, if he determines that an anesthetic is necessary for the performance of the operation, to determine what anesthetic is necessary and the manner of its administration, and to give the necessary directions for so doing and to supervise and direct its giving, and in the selection of an assistant to administer the anesthetic he should exercise the same degree of knowledge, skill and care as he is required by law to exercise in the performance of any part of the operation.

Insufficient Evidence of Malpractice in Treatment of Injured Wrist

(Dishman vs. Northern Pacific Beneficial Association et al. (Wash.), 164 Pac. R. 943)

The Supreme Court of Washington reverses a judgment that the plaintiff recovered in this case, against one of the surgeons of the beneficial association, for alleged malpractice and negligence on the part of the surgeon in failing to operate on and suture the injured extensor tendons of the plaintiff's left hand and wrist. The court says that of the eight physicians and surgeons testifying, other than this defendant, three were of the opinion that the extensor tendons were severed, that this defendant should have operated on the injured parts and sutured the extensor tendons, and that in failing to do so he was guilty of such unprofessional and unskilful practice as amounted to negligence, notwithstanding the carpal bones of the wrist were seriously disturbed in their setting, some of them were cracked, and the outer flesh of the wrist and hand was not broken. The other five witnesses, of apparent equal skill and learning in their profession with the foregoing three, were of the opinion that the extensor tendons were not severed, and that this defendant not only did not fail to exercise a reasonable degree of skill and judgment in not operating on the injured parts, but that his treatment of the injury was in their opinion such as the judgment of a skilful and prudent physician and surgeon would, under all of the circumstances, have dictated. Not only that, but the opinion of these physicians and surgeons was in substance that the defendant would have been pursuing the correct course in not operating on the injured parts, even had he been of the opinion that the extensor tendons were severed, in view of the serious injury to the carpal bones of the wrist and the fact that there had been no breaking of the outer flesh and skin. Such were the conflicting views of the learned doctors testifying in this case touching this manifestly intricate and delicate question of surgical science. To allow a jury or court to award damages against a physician for failure to perform such a delicate and risky surgical operation, when learned men of the profession have conflicting views touching the advisability of performing such an operation as appeared by the evidence in this case, would be, indeed, to allow the awarding of damages to rest on mere speculation and conjecture. The court has not noticed the testimony of these learned doctors at such length as it has for the purpose of determining which entertained the correct and which the erroneous opinion touching the defendant's treatment of the plaintiff's hand and wrist; but their testimony has been noticed by the court with a view of demonstrating that neither the defendant nor any other physician could, in the light of the plaintiff's injury and in the light of medical and surgical science, as the evidence in this case showed, have determined with any degree of certainty whether the treatment he pursued or the surgical operation which it was claimed he should have performed would have produced the better results. Had he operated, as it was claimed he should have done, and the result been no better than the treatment he gave, or worse, as the testimony of a majority of these learned doctors seemed to indicate, there would have been just as good ground for the plaintiff to rest a claim of damages on against him as that on which the plaintiff's present claim of damages was rested. This court has recognized the law to be that a physician is not an insurer of a cure in cases of affliction under his care for treatment, and that he is not to be held liable as for negligence or malpractice for the mere failure to cure, or for bad results because of his choosing one of two or more methods of treatment, when such choosing is an exercise of honest judgment on his part, and the method so chosen is one recognized by the medical profession as a proper method in the particular case, though it might not meet the unanimous approval of the medical profession.

Invalid Provisions for Revocation of Certificate

(Jewell vs. McCann et al. (Ohio), 116 N. E. R. 42)

The Supreme Court of Ohio reverses judgments of the court of common pleas and of the court of appeals that sustained a demurrer to the plaintiff's petition to enjoin the state medical board and its secretary from holding any hearing on, or making any finding or order with reference to, an application in the office of the board for the revocation of the plaintiff's certificate which authorized him to practice medicine and surgery. The court says that by the demurrer the question was presented whether the statutes which authorized proceedings to revoke the certificate, being Sections 1275 and 1276 of the General Code, were violative of the due process of law provisions of the state and federal constitutions. At the time of the commencement of this action, Dec. 18, 1914, those sections provided:

> "Sec. 1275. The state medical board may refuse to grant a certificate to a person guilty of fraud in passing the examination, or at any time guilty of felony or gross immorality, or addicted to the liquor or drug habit to such a degree as to render him unfit to practice medicine or surgery. Upon notice and hearing, the board, by a vote of not less than five members, may revoke a certificate for like cause or causes.
>
> "Sec. 1276. An appeal may be taken from the action of the state medical board refusing to grant, revoking or suspending a certificate, for the causes named in the preceding section, to the governor and attorney general, whose decision affirming or overruling the action of the state board shall be final."

Thereafter these sections were amended and supplemented; but, by reason of the provisions of Section 26 of the General Code, the statute as amended and supplemented subsequent to the institution of this proceeding could in no wise affect this case. The only authority possessed by the state medical board in the matter under consideration, at the time it attempted to take the action sought to be enjoined in this proceeding, was conferred by the sections above quoted. No provision whatever was made or then existed whereby the attendance of witnesses could be required or their testimony procured, nor was any procedure provided whereby the rights of the holder of such a certificate to engage in the practice of medicine could be protected and safeguarded. Although the statutes authorized the revocation of such certificate "upon notice and hearing," the board was not vested with any of the powers essential to the conduct of the trial or hearing. No process was authorized and no method or means for such hearing prescribed or provided, nor was an opportunity to be heard furnished by the provisions of Section 1276 authorizing an appeal to an officer or officers in whom was vested no authority to subpena witnesses, enforce attendance, compel the giving of testimony, or the production of necessary books, records and documentary evidence. The statutes in question did not provide the plaintiff due process of law, and are therefore invalid. The demurrer to his petition should have been overruled.

DELAWARE STATE MEDICAL SOCIETY

One Hundred and Twenty-Eighth Annual Meeting, held at Middletown, Oct. 8-9, 1917

The President, Dr. James Beebe, in the Chair

A Plea for Medical Supervision of Schools for Delaware

Dr. James Beebe, Lewes: As a member of a local draft board I found that the percentage of physically deficient young adults was apalling. The most impressive fact in this connection was that most of these defects could have been corrected by proper treatment early in life. I have observed that, as a rule, the family physician rarely pays attention to the children of a family other than those suffering from an acute illness. The only logical way to reach these cases is by medical inspection of children in the schools. Such inspection also leads to the early discovery of contagious diseases and provides for proper sanitary measures.

Traumatic Rupture of Spleen; Pancreatic Cyst; Bullet Wound of Bowel

Dr. John Palmer, Wilmington: A boy, aged 19 years, fell from a cherry tree. He had almost no external evidence of injury but was unconscious. The next day he suddenly showed symptoms of shock as from internal bleeding. On operation the spleen was found ruptured and still bleeding. The region was packed for six days and the patient made an uneventful recovery. A pancreatic cyst in a man, aged 30, was drained of about 5 quarts of fluid and packed, and within five weeks recovery was complete. A boy, aged 15 years, had a pistol shot wound of the abdomen. By roentgenoscopy the bullet was located in the posterior part of the pelvis. At operation, a hole was found in one side of the lower part of the ileum. This was sutured, and recovery was complete. A later roentgenogram did not show a bullet. The presumption is that it had lodged in the intestine and later passed out by the bowel.

DISCUSSION

Dr. William J. Marshall, Milford: Dr. Palmer's cases have been unusual. Up to 1890, no operations for ruptured spleen had been performed, and the mortality rate at that time was 84.6 per cent. The operation of choice is supposed to be a partial or total splenectomy. But in operating we are not after mechanically successful operation but results.

Pneumonia

Dr. Joseph W. Bastian, Wilmington: Pneumonia is a self-limited disease for which we have no specific. The most promising treatment is with serum which, however, is still in the experimental stage. If any local application has any effect it is the ice bag. These patients should be fed more liberally than was formerly done. Serum should not be used unless we first determine the variety of pneumococcus that causes the disease. Digitalis and strychnin are useful.

DISCUSSION

Dr. H. W. Briggs, Wilmington: All pneumonia patients do better in fresh air, but the temperature of the air should be such as not to create discomfort.

Dr. I. J. MacCollum, Dover: I believe in the use of counterirritation over the chest both in bronchopneumonia and in lobar pneumonia. I do not favor the ice cap in pneumonia. The only time an ice cap is permissible in pneumonia would be in the first twenty-four hours, as it is in all inflammatory local conditions in which one is attempting to prevent more congestion, and it does help in the progress of the disease. After that time it leads to stasis and is a hindrance rather than a help.

Dr. Robert B. Hopkins, Milton: We still are undecided as far as specific treatment is concerned, yet my treatment has consisted of elimination. I do not object to giving half an ounce of compound jalap powder. By that we drain the system. I believe we relieve the congestion to a certain extent, and, while pneumonia is a specific disease, I believe that pneumonia is also a mechanical disease. If we can relieve the portal circulation, we place the men in a better position for recovery. I have used largely ammonium chlorid combined with syrup of ipecac. I did not lose a pneumonia patient last winter.

Dr. J. W. Bastian, Wilmington: It has been conceded that patients do better with abundance of fresh air, comparatively cold; that is, hearty, robust patients. Unless there are some contraindications we put the patients on the porch with hoods on and their hands well protected by mittens. After being on the porch for a few hours, the majority request to be left there. The ice cap is, as a rule, kept on only for the first twenty-four hours. I am unable to see wherein the large doses of purgatives would have any particular advantage. If a man has had personal experience with large doses of purgatives, he realizes their effect. I think high rectal irrigations are better.

Leukemia

Dr. John W. James, Dover: I would urge the importance of blood examinations in cases of anemia. If this were done we should much less often fail in diagnosis. The three agents most commonly used in the treatment of leukemia are the roentgen ray, benzene (benzol, C_6H_6) and radium. The roentgen ray has probably given the best results, but the results of radium treatment have likewise been wonderful. Nothing, however, has been found to be curative. Good results cannot be obtained unless the patient will keep under constant treatment.

DISCUSSION

Dr. Joseph P. Wales, Wilmington: Year before last I had a very interesting case of leukemia. The patient has been practically well for a year and a half. The spleen was down in the pelvis. She had an uncommon symptom, that is, a very large pleural effusion on the left side. I had to aspirate eight times. The treatment was by the use of roentgen ray. Her spleen is now normal. She weighs 200 pounds, and is the picture of health.

Recognition and Treatment of Some Common Injuries and Diseases of the Eye

Dr. W. O. La Motte, Wilmington: In all eye conditions, the eye should be examined carefully. The treatment first adopted largely determines the outcome. Foreign bodies under the lids should be looked for. In looking for a foreign body on the cornea, rays from daylight or artificial light should be concentrated on it by means of a 3 inch lens, and if a foreign body is found, it should not be removed with a toothpick, and a cotton applicator should not be rubbed over the cornea. The foreign body should be removed with a sterile spud. Lime is a common cause of burns, and all foreign particles should be removed, which is best done by forcible irrigation of the conjunctival sac with clean water. Subsequently olive oil or sterile petrolatum should be instilled, and if the cornea is much inflamed, atropin should be used to prevent iritis. In all suspicions of entrance of a foreign body, as a piece of steel, a roentgenogram should be made. By Sweet's method its exact location can be found. Syphilis is the most common cause of iritis. Tuberculosis is second. Traumatism may be the exciting cause. Rheumatism is a doubtful cause. It may be caused by disturbance in metabolism or by absorption of toxins from the gastro-intestinal tract. Many cases of so-called rheumatic iritis are gonorrheal. Iritis should not be treated for conjunctivitis, as is often done, for it may mean the loss of an eye. Glaucoma is a disease that should always be kept in mind, because of the importance, among other things, of not using atropin in such an eye. Strabismus should be treated early by proper glasses, muscle exercises, etc. Eighty per cent. of these patients can be cured without operation if proper treatment is instituted early enough and carried out. Functional headaches are due to eyestrain in 75 per cent. of the cases. In gonorrheal ophthalmia, the conjunctival sac should be irrigated from every half to one hour day and night. Once a day after the eye has been cleansed, the conjunctiva should be treated by being brushed over with a 2 per cent. solution of silver nitrate, and then the excess of the drug washed away with physiologic sodium chlorid solution. Then the lids should be greased with petrolatum.

Fraternity and Cooperation

Dr. Peter W. Tomlinson, Wilmington: Envy, jealousy and ungenerous rivalry too frequently scandalize our ranks. Our love and loyalty to our great and honorable profession require us to accord to every accredited confrère a square deal and a fair field, and even compel us to spread a magnanimous mantle of courtesy and charity over minor deficiencies and unpleasant peculiarities. We must regard our brother's art and accomplishments in the spirit of family pride. We must count his discovery or invention as a victory for the profession. His honor is ours. Our gains and losses are both mutual and individual. His personal achievement is a professional asset. A profession is a fraternity. Ours is the most confidential and sacred profession in the secular world, dealing as it does with the most sacred and secret interests and relations of individuals and families, and frequently determining the question of life and death. The very heart of fraternity is cooperation. How often we forget this and outstretch all other professions in ungenerous competition and relentless rivalries. Competition means selfish isolation. Cooperation means friendly associations.

INTERSTATE ASSOCIATION OF ANESTHETISTS

Meeting held at Toledo, Ohio, Oct. 9-11, 1917

(Concluded from page 1647)

Ether and Etherization in Relation to Infection and Immunity

Dr. William D. Haines, Cincinnati: For the past two and a half years we have used ether intraperitoneally in all operative cases in which peritonitis was present. In forty-three recent cases the mortality was 9.13 per cent. In the total of sixty-six cases there occurred seven deaths, or a mortality of 10.4 per cent. for the entire series, which included gastro-intestinal perforations, gunfire and stab wounds, abortions, leaking pus tubes, and tuberculous peritonitis. In a number of the more virulent cases, ether was introduced through the drainage tube several times during the first and second days after operation. Postoperative complications, including shock, prolonged anesthesia, vomiting, dilatation of the stomach or heart, septic thrombophlebitis and gaseous distention of the intestine were not more frequent, severe or prolonged than in similar cases in which operation was performed prior to the adoption of ether in the treatment of peritonitis. Encouraged by our results, we have gradually enlarged the field of application to other infected regions of the body. Personal experience gained by reopening the abdomen for ileus and other postoperative conditions has led me to conclude that the formation of adhesions is dependent on some inherent condition in the patient's constitution rather than on the type of infection or the use of ether intraperitoneally. I have observed no instances of immediate or remote toxicity, sloughing or increased drainage due to the use of ether. Changes in dressings have been less frequent, toxemia has been more rapidly controlled, and recovery has been hastened by the use of ether, in quantities regulated by the age and condition of the patients.

Perfected Open Etherization and Its Utility in Routine Surgical Procedures.

Dr. Isabella C. Herb, Chicago: Etherization has become popular and prevalent as a safety-first precaution against chloroform fatalities. Open etherization has superseded other methods of administration because of its simplicity, efficiency, safety and freedom from untoward complications. My experience has convinced me that the method has a wider scope of utility in routine surgical procedures than any other technic of narcosis. Dissatisfaction with the method is invariably due to faulty technic. Induction may be facilitated by means of nitrous oxid-oxygen, ethyl chlorid or ethyl bromid, but these adjuncts are not necessary for a pleasant induction if etherization is not pushed. This method is not fool-proof. When ether alone is administered properly, the induction of narcosis by the open method is comparatively comfortable; the blood is well oxygenated throughout narcosis, and the patient leaves the operating table with normal respiration and normal color. Barring operations requiring insufflation anesthesia, the open method is suitable for any patient or operative procedure in which ether is the anesthetic of choice. Experimental evidence shows that with the open method of etherization there is less injury to the lung epithelium than when closed or semiclosed methods are employed. The conservation of body heat during narcosis is of greater importance than the warming of the ether vapor.

Vapor Anesthesia, with Special Reference to Ether-Oxygen

Dr. John J. Buettner, Syracuse, N. Y.: While vapor or insufflation anesthesia has its broadest scope in nose, throat and mouth operations, it is serviceable for many other procedures, and is advantageous in certain types of hazardous risks. The tendency from the start has been to stabilize vaporization by heating, and to promote increased safety by the use of oxygen as a vehicle. Asphyxia may be produced by a lack of oxygen as well as by an excess of carbon dioxid. For simplicity and convenience I now use an oxygen autogenor to which is attached a three-bottle anesthetic device capable of providing a washed, moist ether, chloroform or combined vapor with oxygen, through nasal tubes or mouth hook.

Low Pressure Nasal Administration of Nitrous Oxid-Oxygen

Dr. M. Ecker, New York: For those who of necessity do many oral operations under a personally conducted anesthesia or analgesia, an apparatus that gives a perfectly controlled and visibly gaged flow of gases, and a nosepiece that delivers what the apparatus feeds without demanding the attention of the operator's hands are essential requisites for successful analgesia and anesthesia with nitrous oxid-oxygen under low pressures. By using low pressures, which supply sufficient amounts of the anesthetic to meet the respiratory demands of nose and mouth breathers, without loss by forcing, a decided element of economy is introduced in this somewhat expensive form of anesthesia. Just sufficient flow and pressure to meet the patient's respiratory capacity will obviate loss by respiratory wastage or air admixture, while forcing will promote such loss. The rebreathing bag attached directly to the nasal inhaler facilitates free respiration under normal pressure, secures the desirable carbon dioxid content, serves as a guide to the depth and frequency of respiration, and promotes the economical use of the anesthetic gases.

Local Anesthesia for Certain Operations

Dr. Leigh F. Watson, Chicago: When the field of operation cannot be absolutely blocked or obtunded, local anesthesia is contraindicated and should not be attempted unless all painful periods of the procedure are offset by general anesthesia. Such combined narcosis is invaluable under questionable circumstances. As the technic of infiltration and nerve blocking is perfected, local and conductive anesthesia are being utilized for many major operations previously contraindicated.

Nitrous Oxid-Oxygen Analgesia and Anesthesia in Obstetrics

Drs. C. E. Turner and W. I. Jones, Columbus, Ohio: Nitrous oxid is the ideal agent for the relief of labor pains. It is inhaled as readily as air, is practically odorless, almost instantaneous in its analgesic action, and is eliminated before the next uterine contraction occurs. By varying its dosage, one may so accurately control the administration of nitrous oxid as to offset the increased or decreased distress of each individual pain. Its flexibility and rapidity of elimination make nitrous oxid analgesia preferable to hypodermic amnesia (twilight sleep) and chloroform à la reine. Nitrous oxid-oxygen has practically no contraindications in labor.

Anesthesia in the Surgery of Epileptics and the Control of Status Epilepticus

Dr. G. Kirby Collier, Sonyea, N. Y.: In operating on these epileptics we have in the majority of instances used open etherization by the drop method and have found it efficient, pleasant and safe. We have not noted even minor seizures during the induction period of narcosis, except in a few cases, and in these the attack could scarcely be termed a petit mal. Our results are in rather striking contrast to those of other observers who initiate induction with nitrous oxid and then switch to etherization. Nor have we noted seizures during the operative period, irrespective of the location of the operative field. In the mentally weak or dull, we have sometimes found it tedious to secure cooperation, but the reaction to the anesthetic has always been the same. If difficulty arises it is most probably due to misunderstanding or dulness, and not to any physiopathologic distinction. For some time we have also been using chloroform in the control of the convulsions of status epilepticus, in association with other procedures and remedies. Chloroform is given to control the initial convulsions as immediately as possible. We have found this an efficacious routine and comparatively free from danger, although in one instance the use of chloroform probably played a part in the production of a delayed toxemic poisoning, or precipitated an acute exacerbation of an already existing acidosis. This is the only untoward experience we have had. The utility and value of chlorform in status epilepticus is in direct ratio to the opportunity of administering it as early as possible in the attack. Thus administered, in conjunction with high colonic flushing, and sedatives, it is frequently a life-saving measure.

3. **Effect of Ether Anesthesia on Catalase Content of Blood.** —Burge found that the catalase content of the blood decreases during the administration of ether and increases during the recovery from ether. The decrease is due to the destruction of catalase by ether, the increase to an increased output of catalase from the liver. The decrease in catalase during the administration of ether may be the cause of the decreased oxidation during anesthesia, while the increased output of catalase from the liver during recovery may account for the increased oxidation during this period. Blood catalase is destroyed in vitro by exposure to ether vapor, as happens in vivo during the administration of ether; however, in the former case catalase is not restored to the normal amount when the ether is removed by bubbling air or oxygen through the blood, as occurs in vivo when the animal is permitted to recover from the effect of ether by breathing air. The catalase content of the blood can be increased by prolonging the excitement stage of ether anesthesia or by stimulating electrically the splanchnic nerves distributed to the liver. The increase in catalase may account for the increased oxidation during the excitement stage of ether anesthesia, just as the decrease in catalase may account for the decreased oxidation during the rest of the stages.

4. **Factors Influencing Interchange of Fluid in Blood.**—According to Scott the hemoglobin content of the blood is rapidly modified by any alteration in blood pressure, a rise of pressure leading to an increase of hemoglobin and a fall to a decrease. These results can only be explained by the increased pressure forcing fluid out of the blood to the tissue spaces and the passage of fluid back from the tissue spaces to the blood when the pressure is lowered.

5. **Id.**—The authors state that there is an increase in the water content of muscle as a result of contraction if the blood is circulating through it. There is an increase in the hemoglobin content and in the blood count as a result of muscular contraction. This is due to the passage of fluid from the blood to the muscles. In some experiments the alterations found for the hemoglobin and for the blood count are not exactly the same. The authors believe this is due to technical errors and has no physiologic significance.

6. **Albumoses in Tissues and in Blood.**—Albumoses can be isolated in varying amounts from the tissues of the body, inclusive of the cellular elements of the blood. The methods employed did not, however, enable the authors to separate a proteose of any kind from the plasma of the blood. To prepare an albumose from the gastric or intestinal mucosa which is entirely devoid of pharmacologic activity (pressor, oxytocic and secretory) requires the employment of numerous chemical procedures, as outlined in this paper. The gastro-intestinal mucosa can be washed free of soluble adherent substances, such as the proteoses. The authors feel justified in assuming that what cannot be washed away must be truly a part of the mucosa. The gastro-intestinal mucosa contains from three to five times as much albumose during digestion of meat as after deprivation of all food (except water) for four days. In view of this finding the authors cannot accept the theory that proteins are taken up by the absorbing surfaces of the digestive apparatus only in the form of amino-acids, but must believe, rather, that proteoses as well as amino-acids are freely absorbed, as has long been maintained for the former by certain investigators. While they are able to trace the further passage of amino-acids from the mucosa to various organs via the blood current, they find it impossible at present to do this with proteoses. These cannot be traced further than into the absorbing mucosa, unless it should be assumed that the cellular elements of the blood are distributing agents for them—a point of view which they are at this moment not justified in advancing. The details of the fate of the absorbed proteoses still remain to be determined.

7. **Effect of Temperature on Rhythm of Excised Intestine.**—The evidence presented by Taylor and Alvarez indicates that the rate of rhythmic contraction is determined by the chemical changes taking place in the muscle. The difference in the coefficient for the four different segments implies a difference in their metabolism.

9. **Physiology of Respiration.**—The blood in the pulmonary capillaries contains less carbon dioxid during inspiration than during expiration. The alveolar air receives a greater amount

of carbon dioxid during inspiration than during expiration. The greater amount of the carbon dioxid given off during the respiration cycle occurs at a pressure less than the mean; the less amount is given off at a pressure above mean. The alveolar carbon dioxid tension rises relatively more rapidly during the termination of inspiration and during the first part of expiration than during the latter part of expiration. This condition is due to the fact that during the first part of expiration the pressure of carbon dioxid is less than in the latter part, inasmuch as the total volume of air is reduced by the expiratory act, and each added increment of carbon dioxid is added to progressively decreasing amounts of air, and accordingly the percentage of carbon dioxid mounts very rapidly; even though the actual evolution of carbon dioxid from the blood is less at high partial pressures of carbon dioxid than at low pressures. The rate of oxygen intake of the blood is practically constant during both phases of the respiration at ordinary barometric pressures. A method based on theoretical grounds is proposed by Pearce for the determination of the gaseous composition of the alveolar air and for the capacity of the dead space for both oxygen and carbon dioxid. He believes that the results obtained by this method give very accurate values for mean tensions of carbon dioxid and oxygen in the alveolar air. Samples obtained by the Haldane-Priestley method give figures 6 to 15 per cent. higher for carbon dioxid, and 9 to 20 per cent. higher for oxygen absorbed than are obtained by this method. The dead space determined by this method fails to show as great variation as when determined by the Haldane-Priestley method, and the dead spaces for oxygen and carbon dioxid are of the same magnitude within the experimental error.

10. **Oxygen and Carbon Dioxid Dead Space in Man.**—The experiments outlined by Pearce and Hoover, together with the correct calculations of the data of Haldane, show that deep breathing, which is controlled by needs of the body, does not alter the dead space or "virtual dead space" of Henderson. When the respirations are controlled by the respiratory center and not of extreme depth: (*a*) The dead space is relatively fixed anatomic and physiologic entity. (*b*) The dead space for carbon dioxid and that for oxygen are essentially the same under all conditions. The variations which Haldane, Henderson and their associates find in the capacity of the dead space on deep breathing, and the lack of agreement between carbon dioxid and oxygen dead spaces, are attributable to faulty methods and artificial modes of breathing. The Haldane-Priestley method for the determination of the dead space for oxygen or for carbon dioxid is inaccurate. As great variations in the dead spaces as those found by Haldane and Henderson can be obtained by other methods of altering the respiration than by increasing the depth of breathing. The determination of the percentage of oxygen in the alveolar air by the Haldane-Priestley method is subject to greater error than that for carbon dioxid and any figures obtained by it for oxygen tension in the alveolar air during exercise or at reduced barometric pressures are untrustworthy.

14. **Bone Changes in Leprosy.**—The bone changes in leprosy observed by Honeij vary from slight thinning, atrophy or periostitis to advanced changes with total absorption of phalanges, marked inflammatory action in bone, distortion, ankylosis and fractures. Changes may begin in the periosteum, articular surfaces, corticalis or medullary canal, and apparently any of these changes or all of them may occur in the same set of bones. Also the bones of the hands and feet show the changes soonest and to the greatest extent. The tibia was in one case markedly affected, but in a number of cases the ankle joint bones were not affected. A curious exception in the hands was the thumb, the bones here being in but a few cases slightly affected. The changes in the nerve type are atrophic and in the nodular type inflammatory or hypertrophic. In these particular cases the reverse has occurred and both types of changes have appeared in each form. Periostitis is common. In the absorption process the epiphysis suffers first and most. Cyst or cavity formation is greatest in the diaphysis. Ankylosis occurs, but not healing of fractures, in which salt deposit is necessary. Ulceration of the skin is not necessary, as marked periostitis occurs without any discoverable lesion in the tissues outside the bone. Definite atrophic bone changes, without apparent change in the contour of the phalanx and periosteum, do occur. Atrophic bone changes occur in cases of nodular leprosy; demonstrating the fact that definite nerve disturbances are as much a part of nodular leprosy as inflammatory bone absorption is a part of the process in nerve leprosy. Not in a single case can it be definitely said that the destructive bone process arises internally or externally, for in a single case a periostitis may exist in one phalanx, while in another phalanx the changes are wholly medullary.

24. **Cholecystectomy to Avoid Adhesions in Gallbladder Surgery.**—In a well performed cholecystectomy where no bile is split in the cavity and no drain of the liver is used, Willis says, the trauma of operation seems to be an insignificant factor in stirring up adhesions. On the other hand, in cholecystostomy and cholecystectomy where a drain is used and there occurs spilling of bile, adhesions invariably follow. From the results of his experiments Willis feels that bile is an important factor in the production of adhesions, and that it is of the utmost importance that the irritating and often infected bile should not be allowed to come in contact with peritoneum.

25. Absracted in The Journal, Jan. 13, 1917, p. 145.

26. **Operative Treatment of Hour-Glass Stomach.**—In view of the fact that gastroplasty is often unsuccessful in wide-

spreading ulcer and gastrogastrostomy is relatively dangerous in the presence of much tension, Webb is of the opinion that double posterior gastro-enterostomy is a logical operation and is definitely indicated in certain cases. He cited one successful case.

27. **Radical Removal of Carcinoma of Stomach.**—According to Thalhimer and Wilensky, in small carcinomas of the stomach, situated elsewhere than at the pylorus, the malignant process is so limited in extent that local resection at a distance of from one to two centimeters beyond the macroscopic limits of the tumor will, in the majority of instances, remove the entire tumor. Even in some of the comparatively large tumors included in the authors' study there was no extension of the tumor detectable by the microscope beyond this limit. When a malignant tumor is situated at the cardiac end of the stomach, the surgeon may either perform a complete gastrectomy or consider these cases inoperable. The serious consideration of complete gastrectomy is almost forbidden in these cases because of the high mortality of this operation. Local excision of the tumor is a far less dangerous procedure, and, since the authors' investigations have shown that such local excision is sufficient for the removal of the malignant process, these tumors become accessible for radical operative treatment. Of course such excision is only radical provided no metastases are present.

28. **Hyperplastic Pyloric Stenosis.**—Palmer reports on thirteen cases of congenital pyloric obstruction. In three of these further observation was advised; one patient died suddenly while waiting for the mother's permission to operate, and of the remaining nine, on three gastrojejunostomy was made, and on six the Rammstadt operation. Eight of the nine patients operated on had a marked tumor formation at the pylorus that could not but produce a decided obstruction to the passage of food. The average age of the eight living operated patients when last heard from was 7⅘ months, and the average weight was 17⅘ pounds, or nearly 1 pound above the average given in Holt's book.

35. **Ultimate Results Following Nephropexy.**—While the results obtained by Clark and Block are said to be by no means perfect, they nevertheless present a 70 per cent. restoration to active efficiency of the women operated on, a degree of restoration which compares favorably with many other operations generally accepted by representative surgeons. The authors call attention to the fact that the kidney, particularly the right, is not a fixed organ, and even an excessive range of mobility is no certain index of a reflex gastric or nervous disability unless direct renal symptoms referable to the kidney itself are present. The three cardinal symptoms of disturbed renal function are pain in the renal area; a urinary or Dietl's crisis, due to kinking of the ureter; or vesical irritability directly referable to the kidney of the affected side. No diagnosis should rest solely on palpation of even an unduly movable kidney or on a definite symptomatology unless this is confirmed by a cystoscopic examination, catheterization of the ureters, and a pyelograph to define the point of kinking in the ureter and the degree of dilatation of the renal pelvis. With this rigid method of exclusion and clear symptomatic definition the surgeon may confidently count on securing 70 per cent. of cures and from 10 to 15 per cent. of improvements as the result of the operation. The dangers arising from the injection of roentgenographic substances into the renal pelvis are great if piston or excessive gravity pressure is employed during the injection. With slight gravity pressure no untoward symptom has been observed in their series of cases. In the hands of the authors the Edebohls method, with slight modification, has proved satisfactory as a permanent means of anchorage.

37. **Excising Head of Humerus.**—The operation described by Thomas was performed in one case of recurrent dislocation of the shoulder and in one of old unreduced dislocation. It does not disturb any of the muscles except the subscapularis, which is divided, but later is reunited. Only the cartilage covered portion of the humeral head is removed by sawing through at the anatomic neck. This prevents recurrences of the dislocation, because it removes the only portion which can be dislocated, while it does not disturb any of the muscle attachments except that of the subscapularis, which reunites closely later. In the old unreduced dislocation this operation removes the bony obstruction to the ascent of the remaining portion of the humerus to its normal level just below the acromion process.

39. **Uric Acid in Gout.**—The authors' studies on the intravenous injection of uric acid and the feeding of nuclein containing material, together with the compilations they have made from reports in the literature, show that in normal and nongouty as well as in gouty persons there is great variability in the quantity and in the duration of exogenous uric acid excretion. For this reason a diminished or a protracted exogenous uric acid output most probably results from factors other than disturbances in the nuclein intermediary metabolism. If this is not true, then derangements in nuclein metabolism are so common that their importance in the etiology of any diseased condition is problematic. In the majority of gouty persons the uric acid in the blood is more than 3 mg. per hundred c.c. when determined by the method of Folin and Denis. No relation exists between the amount of uric acid and of total nonprotein nitrogen found in the blood of gouty persons. A marked retention of nonprotein nitrogen is not frequent in gout. The excretion of exogenous uric acid by normal, by arthritic, and by gouty persons varies greatly both in amount and in duration. The retention of exogenous uric acid is regarded as a symptom of questionable importance in the diagnosis of gout.

42. **Phenolsulphonephthalein Absorption.** — Mehrtens and West summarize their paper as follows: Phenolsulphonephthalein when injected into the subarachnoid space in normal persons appears in the urine in ten minutes or less. Diseases of the central nervous system, especially when involving the meninges, produce a lengthening of the appearance time to as much as seventy minutes in some cases. This delay cannot be accounted for by disease of the kidneys, or by the reduction of the phenolsulphonephthalein in the spinal fluid. Advanced general arteriosclerosis may be a factor in causing the delay in some instances. In syphilis a lengthening of the appearance time may be produced before any other evidence of central nervous system involvement has appeared. The method may prove of value in detecting instances of organic central nervous system disease in which the ordinary spinal fluid findings are negative or incomplete. At this time no definite conclusion can be drawn as to the exact location of the absorbing tissues.

43. **Erythrocytes in Anemia.**—The patient, aged 21, entered the hospital with an ulcer on the leg. The ulcer healed under treatment and after her discharge from the hospital, Dec. 3, 1914, the patient gained in weight and showed general improvement. An ulcer had appeared on the leg at two previous times in her history, the first at the age of 5, and the second at the age of 19. In both instances, with treatment, it soon healed. The third appearance occurred ten months previous to the patient's entering the hospital. Aside from this ulceration the physical examination otherwise furnished

apparently little data of evident significance. Examinations for syphilis or parasites were negative. The blood picture constituted the most striking feature of the case and has been more or less persistent up to date, a period of over two and one-half years. About one third of the erythrocytes instead of presenting the normal disk form are greatly elongated in shape. A large percentage of the latter have a crescentic or sickle-shaped form. Nucleated erythrocytes occurred in all preparations. Some of the normoblasts present a biconcave disk shape. Punctate basophilia occurs in many of the nucleated red corpuscles, but was not observed in either the disk-shaped or sickle-shaped nonnucleated corpuscles. Jolly bodies or Cabot rings were not found. Phagocytosis of erythrocytes is taking place to a certain extent in the peripheral circulation. In culture preparations kept at room temperature it was found that great numbers of the previously disk-shaped corpuscles became transformed into elongated and crescentic elements. The tips of the latter were frequently extended into tapering hair-like processes. During one period of the study, for some unknown reason, the abnormal crescentic forms had temporarily disappeared from the circulation. In culture preparations, however, the erythrocytes still manifested the tendency to assume elongated and crescentic forms. Similar cultures from normal blood and from cases of pernicious anemia, chlorosis and myelogenous leukemia gave only negative results.

An interesting exception was obtained in the case of the patient's father. In this instance the circulatory erythrocytes presented an apparently normal structure, but under culture conditions occasional corpuscles were found to assume elongated and crescentic forms. In culture preparations made by placing erythrocytes from a case of pernicious anemia in the centrifuged serum of the patient's blood, some of the red corpuscles assumed characteristics comparable to those observed in cultures of the patient's blood. The culture reaction of the erythrocytes appears to be specific for this case of anemia, and the manner in which the red blood corpuscles are transformed into the sickle-shaped elements suggests that the phenomenon is in part at least due to an accentuated or abnormal activity of the same factors which in normal hematogenesis are involved in the transformation of the original spherical erythrocyte into a biconcave disk-shaped form.

44. **Cholesterol Content of Human Blood.**—Cholesterol estimations were made by Gorham and Myers in the blood of about 200 patients, suffering clinically from about twenty-five different diseases. Hypercholesterolemia was observed, though not invariably, in arteriosclerosis, nephritis, obstructive jaundice and diabetes. A hypocholesterolemia was found in the cachexia of malignancy and all anemias of the pernicious type. The low cholesterol values encountered in the blood plasma of patients with pernicious anemia are regarded as of considerable significance, especially in view of the strong antihemolytic action of cholesterol. The findings in cholelithiasis were quite inconstant. Since hypercholesterolemia may be found in many conditions and is not uniformly constant in cholelithiasis, it would seem that the blood cholesterol possessed only a limited diagnostic usefulness in this condition. It is suggested that the estimation may possess some diagnostic value in diabetes, since the cholesterol serves as an easily determined index of any lipemia.

54. **Brain Tumor Showing Extensive Destruction.**—Thompson reports a case of glioma of the brain in a man, 70 years of age, causing extensive destruction of the brain tissue. It involves the corpus callosum, white matter of the left frontal lobe, caudate and lenticular nuclei and internal capsule. The mental symptoms showed themselves by a tendency to wander about, increased irritableness and loss of memory. An early symptom was the loss of control of the sphincters. The history is one of occasional seizures, characterized by pallor, rigidity and confusion, followed by prolonged sleep. As the disease progressed, memory loss and confusion increased. Twenty days before his death the patient was able to walk with a normal gait, and the hand grips, although weak, were equal. Pupils reacted normally and tendon reflexes showed nothing unusual. The eye grounds were not examined. As his mental confusion progressed it became necessary to keep the patient in bed and feed him with a spoon, but no paralysis of either upper or lower extremities was noted; neither were any speech difficulties mentioned. Headache is nowhere mentioned in the case, either before or after admission to the hospital. The case seems interesting on account of the poverty of diagnostic features as compared with the extensive destruction of brain tissue.

77 *Fate of Strychnin in Body. R. A. Hatcher and C. Eggleston, New York.—p. 281.

73. **Action of Alypin, Eucain, Holocain, Novocain and Stovain on Bladder.**—Waddell found that alypin, alpha and beta-eucain, holocain, novocain and stovain stimulate the excised bladder when suspended in oxygenated Tyrode's solution at body temperature. Compared with cocain, the stimulating action of beta-eucain is approximately one-seventh; of novocain, one-sixth; of alypin, alpha eucain and stovain, one-third; and of holocain, two-thirds. Mixtures of the synthetic cocain substitutes with each other give simple summation on the excised bladder. Combinations with epinephrin exhibit simple antagonism and with pituitary extract simple summa-

tion on the excised bladder. Paralysis of the parasympathetic myoneural junctions by atropin does not alter the response of the excised bladder to any of the drugs of this series. The conclusion drawn is that these drugs act on the muscle directly, since their effects are the opposite to those of sympathetic stimulation and are unchanged by paralysis of the parasympathetic myoneural junctions.

74. **Epinephrin Inhibiting Flow of Pancreatic Secretion.**—Experiments conducted by Mann and McLachlin showed that large doses of epinephrin, which produce a marked rise of blood pressure, always decrease the flow of pancreatic secretion. Very small doses usually also decrease the activity of the pancreas regardless of whether a pressor or depressor action of blood pressure is produced. Epinephrin also decreases pancreatic volume at the same time it decreases pancreatic flow, regardless of its effect on the general blood pressure. While it is not stated definitely that epinephrin does not specifically inhibit the pancreatic cells, it would seem that the action of epinephrin in inhibiting the pancreatic secretion depends on the amount of blood passing through the gland. Large doses of epinephrin, even though general blood pressure is greatly increased, decrease the amount of blood to the pancreas by excessive local constriction, and thus decrease the flow of pancreatic juice. Small doses may or may not affect the secretion of the pancreas, depending on whether the relation of the local constriction and the changes in general blood pressure change the amount of blood going to the gland. The pancreatic vessels may constrict with a dose which will produce enough dilatation elsewhere to cause a decrease in general blood pressure, or which may not produce enough general action to affect blood pressure at all. In every case the cause is the same, a reduction of the amount of blood passing through the gland per unit of time. However, these results all tend to accentuate the fact that the pancreatic vessels seem to be more sensitive toward the pressor action of epinephrin than those of any other region concerning which data are available.

75. **Nondependence of Protein Quotient**—According to Hanson and McQuarrie, antipyrin, even in large doses, causes no change in the serum proteins. Substances most intimately related to antipyrin in their pharmacologic action (acetanilid and paramidophenol) have no effect on the protein quotient. Other substances influencing metabolism (*a*) in the direction of retardation (quinin and sodium cacodylate), or (*b*) in the direction of acceleration (thyroid extract), produce no change in the relative proportions of the serum proteins. These experimental results consistently indicate that the quantity of albumins and globulins in the blood serum is quite independent of the rapidity of the nitrogenous metabolism.

77. **Fate of Strychnin in Body.**—Experiments carried out by Hatcher and Eggleston on cats, dogs and guinea-pigs showed that toxic doses of strychnin may be administered at short intervals during periods up to twelve days, the total amounts so administered being equal to twenty-five times the single fatal dose, without causing perceptible lasting effects. Only a small percentage of the strychnin so administered can be recovered from the urine, and none from the feces. The excretion in the urine usually ceases within twenty-four to forty-eight hours. The tissues of the guinea-pig (exclusive of the skin, which was not examined) do not yield any strychnin even after the administration of very large amounts provided that death does not take place within three hours after the administration of the last dose. The facts just stated point conclusively to the rapid destruction of the strychnin in the body of the guinea-pig and almost as conclusively to that in the bodies of the cat and dog.

Perfusion of the liver of the dog and that of the guinea-pig with defibrinated blood or Locke's solution to which strychnin has been added results in the destruction of a large part of the strychnin, and the storage of a greater portion of the remainder than can be accounted for by the proportion of the perfused fluid held in the liver. The strychnin stored in the liver is loosely bound and the greater part of it may be removed by perfusing once with an amount of Locke's solution equal to several times the weight of the liver. Strychnin is not destroyed in all cases when it is added to defibrinated blood or hashed liver tissue and allowed to stand at body temperature for several hours, but there is some evidence that small amounts may be destroyed in this way under slight differences in conditions which Hatcher and Eggleston have not determined. Strychnin is destroyed slowly, or not at all, when it is added to the guinea-pig's intestine and its contents and the mixture is allowed to stand at body temperature for twenty-four hours. Strychnin is not excreted in the bile after its intravenous injection into the dog.

7. **Early Closure of Gunshot Wounds.**—Hey brings forward the use of a mechanical aid to excision of the wound, namely, the staining of the track of the missile with a 0.5 per cent. watery solution of brilliant green and, second, the use of a paste as the method of sterilization. The composition of this paste is the following: boric acid, 11 ounces; French chalk, 1 ounce; liquid petrolatum, 8 fluidounces; brilliant green (1:500), 17½ grains. The boric acid and French chalk are first intimately mixed in a mortar, then the liquid petrolatum is worked in, and finally the brilliant green dissolved in rectified spirit. Considerable time and energy are required to avoid a paste with many isolated masses of boric acid. It is kept in jars and used chiefly from large syringes with very wide nozzle apertures or from grease pumps. Departures from the quantities and constituents of this paste have been invariably productive of worse results. If the chalk is omitted it will not adhere to any but the driest and freshest of wounds, and intimate adhesion to the tissues is an essential quality of a paste. No toxic effects have been observed. A strong, firm scar rapidly results; the skin unites well over a cavity such as is left by a pulped tibia. Extensive wounds of the buttock, and wounds complicated by division of large arteries or by fracture of any of the long bones, have been quickly closed. Fractures have been successfully sutured in three to five days, and wounds dividing muscle have been closed by partial primary suture with safety, which must be the outstanding feature of any method. Hey pleads for complete excision of all wounds; without it good antiseptics and pastes are almost useless in quickly healing the broken skin.

8. **Spread of Infection in Open Bone.**—The following conclusions are drawn by Martin and Petrie with reference to the operative treatment of projectile fracture: Some are already well recognized, none are universally practiced. Soft parts killed by the direct effect of the missile require removal. An infected fracture of the shaft of a long bone requires opening to the full extent of solution of continuity. In infected fracture of cancellous bone the superficial débris of smashed trabeculae, etc., requires removal. Solid bruised bone is able to resist infection and may be left. As penetration is at its maximum in the first few days, early opera-

tion is essential, especially in fractures of cancellous bone involving joints. Every artery directly or indirectly supplying a fractured bone is of importance in the defence against infection. In the presence of vascular injury proximal to the fracture, radical measures, such as amputation or resection of a joint may be adopted with less hesitation.

9. **Method for Efficient Drainage of Knee Joint.**—By means of proper position of the leg Mayo-Robson makes the suprapatella pouch the dependent part of the joint, and by the very simple operation of inserting a tube into the top of the pouch the whole joint can be completely evacuated and purified, and if this is done sufficiently early, a speedy recovery may be anticipated with the joint mobility unimpaired. Two changes of position will make the suprapatellar pouch dependent: (*a*) the vertical position of the limb at right angles to the body with the patient in the dorsal decubitus, or (*b*) the prone position of the body with the foot of the bed well raised. In both positions the limb must be efficiently fixed on a splint, as fixation in inflammation of the knee joint is only second in importance to drainage. If for any reason the vertical position is inconvenient or difficult to carry out, the prone position can be adopted, the foot of the bed being raised and the limb slung from above by pulleys and weights for the thigh and leg. As the prone position is irksome if prolonged, the patient, when once the joint has been emptied, may, if necessary, be turned on his back and the prone position adopted for from half an hour to an hour every four hours at first, and later about three times in the day, until the drain can be dispensed with. When once the joint has been thoroughly evacuated of its septic contents, and if needful gently washed out with warm normal saline solution, the synovial membrane of the knee, like the peritoneum, is capable of taking care of itself. Long continued drainage is very seldom required, and usually a movable joint will be obtained.

17. **Pneumococcal Meningitis.**—Nine cases of pneumococcal meningitis have come under the care of Worster-Drought and Kennedy. In five cases the disease was the so-called primary form; that is, no lesion conceivably due to active pneumococcal infection was discovered elsewhere. Of the five cases, two were infants and two were adults. The adults had had catarrhal colds for three or four days, followed by severe headache, prior to the appearance of meningeal symptoms, while the younger infant had had sudden convulsions. Following the appearance of headache, vomiting occurred in four of the five patients, and delirium rapidly supervened in the two adults. Of the four cases in which meningitis occurred as a secondary infection to a focus elsewhere, in two the primary lesion was a lobar pneumonia, in one middle-ear disease, and, in the last, an empyema of the sphenoidal sinus.

26. **Effects of Cold on Body.**—Lake summarizes his paper as follows: (1) The temperature, 6 C., must be considered critical in relationship to the effects of cold on the tissues. (2) Degrees of cold below this temperature produce true frost bite and actual damage to tissues. (3) Degrees of cold above this temperature only produce effects secondarily by causing vasomotor paralysis. (4) Nerve blocking does not prevent either the effects of frost bite or of chilling. (5) The use of vasoconstrictors delays the swelling in cases of true frost bite, while in cases of chilling the exudation may be entirely prevented. (6) Satisfactory treatment of trench foot must be directed toward preventing any appreciable rise in capillary pressure. (7) In the production of trench foot cold must be considered the essential factor, other factors being either secondary or subsidiary. (8) Treatment by the use of vasoconstrictors, either intravenously or otherwise, would appear logical and worthy of trial. (9) Treatment by nerve blocking, either regional or central, is also suggested, although, in all probability, it cannot be expected to give good results unless used in conjunction with vasoconstrictors. (10) Prophylaxis consists in using any and every means of preventing congestion of the legs, and in avoiding, so far as possible, variations in the temperature. (11) The question as to whether any surgical procedure, such as temporary occlusion of the arteries, would bring about the desired reduction in capillary pressure is being investigated.

28. **Normal Gundeafness.**—Jobson endeavored to ascertain what proportion of soldiers exposed to gunfire go deaf, to measure, so far as possible, the amount of deafness produced in a previously healthy ear, to ascertain whether this deafness is temporary or permanent, and to investigate the type of deafness so produced. Sixty soldiers were examined. Many of the cases gave a history of severe or complete deafness for one or more days after exposure in a big "strafe," but almost invariably said they could now hear quite well. The cases were all infantry men, who would not be so close to big gunfire as the artillery. The conclusion of Lake's study was that exposure to gunfire in the present war often produces rapidly a permanent deafness. This normal—if the author may so call it—gundeafness is of a very definite type—a mixed obstructive and nerve deafness. The amount of deafness as shown by a C 2 fork is about ten seconds, aerial conduction, and four seconds of bone conduction.

40. **Treatment of Shock by Intravenous Injection of Gum Acacia.**—Bailiss is professor of physiology at the University College, London. He here discusses shock with subnormal blood pressure from loss of blood. The first indication, he says, is to restore the blood to approximately its normal volume, viscosity and osmotic pressure. Unless the injected fluid corresponds in these three points, it will fail to that extent in its purpose. In Bailiss' experiments on animals he found that intravenous injection of Ringer's fluid did not restore the blood pressure to normal. But with addition of 6 per cent. gum acacia to the fluid the blood pressure returned to normal. This evidently provided for a normal standard

of viscosity in the circulating blood. Army surgeons are finding solutions of gum acacia useful in the wounded when the drop in blood was due wholly or in part to the losses of blood. Bailiss noticed also in his experiments on animals that even the immediate benefit on the blood pressure from the solution of gum acacia surpassed that from ordinary saline solution, while the effect was permanent. The effect of Ringer's solution was quite transient. A 6 or 7 per cent. solution of gum acacia displays the same osmotic pressure as normal blood in parchment osmometers. The walls of the blood vessels, the same as parchment, are impermeable to colloids, and osmosis proceeds alike in both. When the osmotic pressure of the colloidal substances in the blood is diminished by dilution with a salt solution, filtration through the glomeruli occurs more rapidly than normal, so that the physiologic saline injected intravenously has a tendency to be eliminated in the urine, or it infiltrates into the tissues and may induce edema at various points. All who have made experiments on surviving organs perfused with Ringer's fluid have noticed sooner or later a tendency to edema. This does not occur if gum acacia has been added to the Ringer's fluid. Gum acacia at 7 per cent. or gelatin at 6 per cent. seems to conform to the requirements so far as the viscosity and the osmotic pressure are concerned, restoring practically normal conditions in these respects without danger for the animal. A 4 per cent. solution of gum acacia with 0.9 per cent. sodium chlorid gave excellent results in cats, and a 2 per cent. solution has been successfully used in the clinic. Gum acacia already contains calcium and potassium. This is the highest concentration used on man to date of which he knows.

Gum acacia can be easily sterilized by boiling and filtering through cloth; it is superior to gelatin on this account. It is not supposed to contain proteins, and hence anaphylaxis need not be feared. In shock of other origin, the blood may be abnormally concentrated from loss of water and salts. When this is the case, practically normal conditions can be restored by intravenous injection of Ringer's fluid. If the concentration is due to loss of the whole plasma, then the fluid to be injected should correspond in viscosity and colloid osmotic tension to the blood itself. Ringer's solution with 2 or 3 per cent. gum acacia seems to answer the purpose. There might be conditions in which it would be better to use a colloid with less viscosity but higher osmotic pressure, such as dextrin. The effect of hypertonic saline solutions is only temporary as the osmotic balance between the blood and the tissues is so promptly reestablished. Bailiss' experiments on cats with pulmonary edema, following inhalation of asphyxiating gas, confirmed that continuous administration of oxygen is the logical treatment. In the cats, withdrawal of even a small amount of blood reduced the blood pressure so low that death generally followed. Up to a liter of fluid has been found in the lungs in pulmonary edema in gassed soldiers. Intravenous injection of a 2 per cent. solution of gum acacia seems indicated, but as long as fluid is seeping into the lungs, it only adds to the flood unless we can restore the epithelium in the lungs to normal functioning, and oxygen seems the only reliance here. The suffering and dyspnea may persist, however, until the accumulated carbon dioxid has been thrown off by the amplified respiration.

43. **The Nitrogen Balance.**—Malengreau is professor of physiologic chemistry at the University of Louvain, and in the fourteen pages of this work he discusses the actual significance of the nitrogenous minimum.

46. **Notification of Miscarriages.**—The Académie adopted a resolution at its meeting October 2, in favor of applying to expulsion of every fetus, whatever the age of its intra-uterine life, the regulations already promulgated in the civil code in regard to notification of stillbirths.

48. **Syphilis and Heart Disease.**—Gaucher reiterates that the field of syphilis is being constantly enlarged, especially the affections of what he calls the quaternary stage of syphilis. The inefficiency of treatment in this stage is no argument against the syphilitic origin; we cannot cure tabes, although tabes is certainly of syphilitic origin. He calls attention in particular here to lesions of the myocardium and especially mitral lesions for which syphilis is responsible. He describes a typical case of mitral insufficiency accompanied by vague intermittent pains, exclusively muscular and intermittent, the knee jerks abolished. The man had been long treated for "rheumatism" and digitalis given for the mitral trouble, no one suspecting the unmistakable syphilitic origin of the trouble notwithstanding a history of syphilis years before and the present signs of abortive tabes.

50. **Glycosuria After War Wounds.**—Rathery found glycosuria in 4.17 per cent. of 1,412 wounded soldiers. The range was from 2 to 20 gm. with exceptional cases up to 35 gm. The duration was only for two or three days, except in two cases in which it was respectively two weeks and several months. But it finally disappeared in all. No instance of actual diabetes developing after a war wound has been encountered.

59 *Spirochetosis. Manine and Cristau.—p. 977.
60 *Attempt at Suicide with Epinephrin. R. Grasset.—p. 981.

56. **Vaccine Therapy in Typhoid.**—Ranque and Senez report that in forty-six cases in which the vaccine treatment was commenced during the first week of the typhoid, the febrile phase lasted on an average only sixteen days. In a total of 120 cases they were impressed with the rarity of complication, absence of relapses, and the simplification of treatment as in a large number of the cases no other measures were required.

57. **Differentiation of Diphtheria Bacilli.**—When circumstances demand exact differentiation, cultures on coagulated serum of the true diphtheria bacilli are dry and white, while those of the Hofmann bacillus are moist and yellow. The diphtheria bacilli are slender, with numerous granulations, the rest of the protoplasm of an even and pale tint, not taking or retaining stains well.

59. **Meningeal Form of Spirochetosis.**—Manine and Cristau report 100 cases with spirochetes in the urine and in some in the spinal fluid also. In 51 cases the liver symptoms predominated, in 10 the pulmonary; in 4 the kidneys; 10 were of a rheumatismal and 10 of a typhoidal type and 11 of the meningeal type. There were 4 deaths in this latter group and one in the typhoidal, but there was no other mortality. In 6 of the 11 meningeal cases the spirochetes were alone and in 5 associated with other germs. There was purpura in 3 in the meningeal group, hematuria in one; extreme opisthotonos for two weeks in one and coma from hypertension in one. Recurrence was frequent; several times the lumbar puncture had to be repeated. Emaciation and anemia were pronounced, and spirochetes were often found in the urine during convalescence. Antimeningococcus serum was injected in three cases while the diagnosis was still dubious, and it unmistakably aggravated the clinical picture. In the other cases lumbar puncture, a fixation abscess and fluid by the rectum, saline with laudanum, and balneotherapy were the reliance.

60. **Attempt at Suicide with Epinephrin.**—The tuberculous young janitor of a pharmacy drank 15 gm. of a 1:1,000 solu-

tion of epinephrin (adrenalin) and five minutes later 20 gm., and then took some other solid drug marked poison, nature unknown. No special symptoms followed until by the end of the second hour the back of the neck became rigid and in two or three hours there were tetaniform contractions, extreme congestion of the face and intense headache. The pulse was about 120, full and regular; amyl nitrite and venesection brought great relief after withdrawal of over 500 gm. of blood. Emetics were also given, with caffein and camphor, and chloral to quiet the agitation. By the next day the only symptoms were a dull headache and pain in the epigastrium. The dry poison taken had evidently not been absorbed as the gastric mucosa must have been exsanguinated. The case teaches that the first swallows of the epinephrin expel the blood from the mucosa of the alimentary tract and hence no further absorption is possible and an emetic will obviate further danger. In this case the epinephrin did not begin to be absorbed for two hours. Grasset draws further the practical conclusion that in administering epinephrin by the mouth it should be given in minute doses, not over 0.25 or 0.5 mg. By this means 2 or 3 mg. swallowed in the course of the twenty-four hours will have a more effectual action than 10 mg. taken at one time. The phenomena from the congestion are also practically negligible with minute doses. In the discussion that followed, Netter remarked that he gives epinephrin by the mouth, from 3 to 5 drops in a teaspoonful of water. By this technic the epinephrin is absorbed before it reaches the stomach. When diluted with considerable water, it is liable to be modified by the gastric secretions. Josué prefers to give epinephrin subcutaneously in infectious diseases with failing suprarenal functioning. He adds 1 c.c. of the 1:1,000 solution to 250 or 500 c.c. of physiologic salt solution. Addition of 0.01 gm. novocain prevents the injection from being painful. The epinephrin is absorbed so slowly when given in this way, that it amounts practically to fractioned dosage, and it can be kept up for several days, as long as the condition requires it.

61. **Eczema.**—Bloch remarks that we know today little more about eczema than twenty years ago. As hexamethylenamin generates formaldehyd in the tissues when taken internally, Bloch reasoned that this drug might induce blood-borne eczema in the predisposed. A young physician subject to eczema from formaldehyd externally, took 0.5 gm. hexamethylenamin three times a day and in three days parts of the skin were red and itching. By the end of the week symmetrical areas were covered with typical eczema, most pronounced on the upper arms and shoulders. This experimental eczema gradually subsided on suspension of the drug. This case supplies the hitherto lacking proof that eczema can develop from an internal cause. Our task now is to discover in the metabolism and the body juices the substances which are responsible for the development of eczema. The formaldehyd split off from the hexamethylenamin in the case reported must have been in extremely minute amounts.

70. **Neosalvarsan Eruption Warded Off with Epinephrin.**—Nägeli reports the case of a young man who developed patches of erythema on the face, with smarting in the left eye, fifteen minutes after an intravenous injection of 0.15 gm. neosalvarsan. The exanthem was of the type of the antipyrin exanthem. It subsided in twenty minutes but returned each time after the neosalvarsan during the following months until it was found that a preliminary intramuscular injection of 1 c.c. of a 1:1,000 solution of epinephrin warded off the exanthem. Unless the interval betwen the epinephrin and the neosalvarsan had been at least five minutes, the exanthem developed, and the area affected varied inversely with the dose of the epinephrin. Given by the mouth, no effect was apparent. The conjunctiva of the left eye, the cheeks and the brow responded most sensitively to the irritation from the neosalvarsan, as also the areas around pigmented nevi—all very vascular regions. Nägeli also witnessed excellent effects from epinephrin in arresting the disturbances in a severe case of meningeal irritation after neosalvarsan. Milian introduced epinephrin into treatment of the anaphylactoid attacks after salvarsan, resembling the vasodilator disturbances sometimes noted under amyl nitrite. Nägeli further warded off in this way the violent diarrhea to which three patients were subject when taking mercury. After an intramuscular injection of 1 c.c. of the epinephrin solution, the mercury could be given without the otherwise inevitable diarrhea. In other cases the epinephrin proved equally effectual in warding off symptoms of medicinal intolerance. In only one instance did it fail; this patient at the single trial said that his mercury vertigo was worse after the epinephrin. The neosalvarsan exanthem may be due to a pure idiosyncrasy of the skin alone, or the internal organs may share in it, or the latter alone may be affected first and the skin only secondarily from the toxic products generated in them, especially in the liver. As a typical example of the latter, he cites Neisser's arsenophenylglycerin case with a fatal outcome. The first dose had induced only what seemed to be a pure drug exanthem.

79. **The Ear During the War.**—Brunetti reviews the various causes liable to injure the organ of hearing during the present warfare. He discusses in particular the injuries from explosions without direct contact, and the detection of simulated or exaggerated deafness in one or both ears. This is particularly difficult when there is or has been hysteric deafness. With this, other stigmata of hysteria must be sought; the reactions to electric tests may be modified. An electric shock alone may cure hysteric deafness. General anesthesia has proved useful in some cases and hypnotism in others, or both together. The areas of hypesthesia in the skin are instructive, as also changes in the visual field and inversion of colors.

81 *Color Reaction in Pathologic Cerebrospinal Fluid. L. Chiaravalloti.—p. 577; R. Vaglio.—p. 581.
82 *Organic Nature of and Calcium Metabolism in Chorea. U. Provinciali.—p. 586.
83 Vaccine Therapy for Children. P. Ceppellini.—p. 602. Continuation.

81. **Color Reaction in Cerebrospinal Fluid.**—Chiaravalloti has applied Boveri's color test in thirty cases of various meningeal troubles and normal controls, and expatiates on the simplicity of the technic and the reliability of the bedside findings. [The test was described in The Journal, June 11,

1914, p. 205.] To 1 c.c. of the cerebrospinal fluid is added 1 c.c. of a 1:1,000 solution of potassium permanganate. If the cerebrospinal fluid is normal, the violet tint persists unmodified for some time. With a pathologic fluid, the tint turns yellowish, and the sooner and more intense the phenomenon, the more pathologic the cerebrospinal fluid. He tabulates the findings with parallel tests in his thirty cases, all confirming the other clinical data.

Vaglio confirms these favorable statements and emphasizes in particular the importance of this simple test when there are dubious symptoms and the cerebrospinal fluid is limpid. In thirteen such cases the albumin content of the fluid was only slightly above normal, but this test revealed its pathologic character, confirmed by the course of the cases. He notes further that the reaction does not seem to be modified by the accidental presence of red corpuscles in the fluid. His technic differs slightly from Boveri's as he uses only 1 drop (0.05 gm.) of a decinormal solution of potassium permanganate for 1 c.c. of the fluid, shaking up the test tube.

82. **The Organic Basis of Chorea.**—Provinciali reviews the literature on this topic and describes his personal research undertaken to determine whether symptoms of chorea indicate participation of the pyramidal tracts and cerebellum in the meningo-encephalitis which seems to be responsible for chorea. The manifestations of the disease are so multiple and variable that it is difficult to pass judgment on their source and nature. But with extensive compilations of cases it has become evident that the aggregation of certain symptoms, each insignificant in itself, points more and more conclusively to an organic basis. Cerebellar elements in the clinical picture are hinted in over half the cases. Three cases are described in detail with the findings as to metabolism of calcium compared with a normal child, all on a constant diet. In the child of 7 there was little deviation from the normal type, but in the girl of 14, instead of retention of over 30 gm., only 0.918 gm. was retained and nearly 4 gm. eliminated in urine and feces.

90 Trachoma in the Army. L. Alajmo.—p. 1191.

84. **Treatment of War Wounds of the Chest.**—Morelli urges the promptest and most complete clearing out of all the blood in the chest, and has devised an apparatus with which the blood is replaced at once by air, thus maintaining the immobilizing compression desired while getting rid of blood, pus, and all secretions. The apparatus for the purpose is a modification of the one devised for thoracocentesis. The illustration shows the two jars with two tubes in the stoppers, connecting tubes, a rubber bulb at one end and a syringe at the other, the aspirating needle connected with the tubing between the jars. The apparatus allows the chest cavity to be rinsed out with a disinfectant if desired. At the beginning of the war, abstention was the rule for chest wounds, but this principle has given way to systematic intervention just as with abdominal wounds. The results are better the earlier it is applied, but mastery of the technic is indispensable.

85. **Coaptation of the Special Fibers in Suturing Peripheral Nerves.**—Barile discusses the practical importance of Stoffel's method of ascertaining the topography of the nerve fibers and suturing like to like. It has been Barile's experience in a number of cases and in experimental research that only the motor fibers of the paralyzed nerve regenerate in the mixed nerves in the limbs after direct electric tests have been applied. On the other hand, time and experience have abundantly confirmed the superiority of his own technic which ensures a large area of coaptated surface, while the nerve fibers, both sensory and motor are left intact. [His method was described in THE JOURNAL, Jan. 11, 1913, p. 170.] He protects the nerve with a piece of the membrane from a hen's egg, boiling first in a gauze bag and then tying it around the nerve, fastening the end of the piece to the connective tissue. This membrane shield lasts long enough before it is absorbed for healing to proceed beyond the stage of adhesions to the nerve. For the anastomosis of the paralyzed nerve, to be grafted on the sound nerve, he cuts the peripheral stump end of the paralyzed nerve in swallow-tail shape, and fits it up into the sound stump prepared to receive it. Each of the swallow-tail tips is fastened in place in the sound nerve with a single stitch. The raw surface between the stumps covers a much larger area than with other technics, and the results, he says, have been most gratifying. The egg membrane is proving a reliable means to protect a nerve after it has been released from a constricting bed of cicatricial tissue.

99 *History of Bubonic Plague. A. M. del Pont.—p. 165. Conclusion.
100 *Pulmonary Tuberculosis in Children. J. C. Navarro.—p. 197.

94. **Shortcircuiting the Lower Intestines in Treatment of Chronic Constipation.**—In the case reported by Ceballos the benefit from ileosigmoidostomy in the young woman was so pronounced that it certainly encourages further trials of this shortcircuiting method in treatment of habitual obstipation. The various other technics for remedying this condition are described with this, and its advantages extolled in cases of constipation for which no cause can be discovered and vagotony or sympathecotony seems to be responsible.

97. **Pancreatic Diabetes.**—Hardoy reports a case in a young man of 21 in whom the pancreatic diabetes had rapidly developed. Certain features of the case suggested an inherited syphilitic taint as responsible for the trouble. The diabetes was of the lean type, of rapid development, with high azoturia and glucosuria, and great prostration. Hardoy recalled that hypertony of the sympathetic system has been incriminated by some in the genesis of glucosuria, but tests in this case failed to reveal any sympathetic hypertony. Certain circumstances suggested that although there was no sympathetic hypertony, practically the same effect was realized by hypotony of the antagonist vagus system. Tests for vagotony gave positive findings, and he tentatively administered pilocarpin to raise the vagotony level to normal. The effect was marked, amply confirming his premises. As the nervous system became habituated to the pilocarpin, the effect grew constantly less. At this point he began vigorous mercurial treatment, and the sugar disappeared promptly from the urine. To confirm these conclusions anew, he brought on the glucosuria again by a change of diet, and banished it promptly anew with pilocarpin. In conclusion he reiterates that syphilis should always be sought in diabetics. He adds that severe diabetes of the pancreatic type, in the young, is liable to improve remarkably under treatment, which might include pilocarpin.

99. **Bubonic Plague.**—This instalment brings to a close Del Pont's long historical sketch of bubonic plague through the ages. In Argentina it seems there were 1,635 cases from 1899 to 1913, inclusive. It appeared also in Brazil for the first time in 1899. Rosario in Argentina is still an important focus, 40 cases in and around it being known in 1914. It had the first case of plague in the country, imported from Paraguay whence it spread to Buenos Aires. But the Salta focus became infected, by way of Chili, from the endemic focus at San Francisco. "This," he adds, "is the city that with its commerce scattered the plague along the entire Pacific Coast of America." The data show, he says, that in Argentina the

disease has not been spread by migration of rats but exclusively by the railroads. The disease always appeared first in the grain warehouses, in warehouses where there are goods in sacks and, predominantly, in the vicinity of railroad stations.

Del Pont's study of the plague through 4,000 years shows that it occurs in waves. It spreads rapidly around the world, following the routes of commerce, and then seems to die out simultaneously everywhere, without known cause. The decline cannot be from attenuation of the death-rate as the mortality in the latter part of the epidemic is as high as at first. It cannot be explained either by acquired immunity, as this would require having passed through a mild attack. When the epidemics declined, scattered endemic foci were always left, as at present in Buenos Aires and Rosario, Rio, Para, Pernambuco and Bahia in eastern South America. But such foci usually die out before long all except a very few. These places shelter the virus until it starts another pandemic. In previous ages bubonic plague killed human beings and domestic and wild animals alike, but of recent years it seems to be pathogenic only for man and certain rodents; at least the latter are the only ones that have the disease naturally. But the virulence of the disease has not been modified. Men die of it now just as promptly as in the days of Thucydides or Procopius.

The present epoch is now characterized by a disquieting persistence of the disease in the scattered endemic foci around the world. Many places that had never had a case ten years ago, have now become actual endemic foci on a small scale. The present epidemic seems to be favored by unhygienic conditions, as in the epidemics of previous ages. The prophylactic measures at present in vogue are effectual only in certain circumstances, and they succeed in extinguishing the disease only in certain localities. In the semibarbarous districts they do no good whatever. On the other hand, the most civilized communities escape with relative facility without much in the line of special measures. As Aubert said in 1840, "the plague must be combated not with lazarets but with civilization." The classic foci hitherto have been parts of southern and northeastern Asia, Mesopotamia, Arabia, the Caucasus mountains, and Kissiba in Africa between the lakes Albert and Victoria, but Del Pont's summary shows now many other equally dangerous foci.

100. **Special Forms of Pulmonary Tuberculosis in Children.**—Navarro describes six cases of chronic pulmonary tuberculosis in children in whom extensive lesions in the lungs did not appreciably debilitate, all presenting the aspect of health. One of the children did not even have a cough. The only constant symptoms were the lack of appetite and the tendency to lassitude. They were usually pale, but one had quite a ruddy complexion. All except one were annoyed by frequent coughing without dyspnea, cyanosis or subjective symptoms. Two of the children were 4 and 5, the others, between 8 and 14. In two, the right or left apex was the seat of the lesion; in the others, the base of the lung.

108. **Is There Sensation of Pain in Animals?**—Van Rijnberk is professor of physiology at the University of Amsterdam. He here remarks that theoretically it is impossible, and practically it is often difficult, to determine whether a human being is suffering pain, and to determine whether an animal can suffer or does suffer pain is even more difficult. Have animals (all animals? one given animal?) mind, reason, consciousness? Have they (all? a given one?) perceptions comparable to those of man? One person regards all animals as merely automatons; another believes that a horse can do examples in arithmetic.

But so far as determination of whether an animal is suffering "pain" or not is concerned, we are exclusively restricted in our judgment to vague signs, such as sounds, movements, and the like as testifying to the presence of pain. We have to bear in mind here that nothing, literally nothing can guarantee to us that in a given case any manifestation which we are accustomed to consider as an expression of pain—nothing can guarantee to us that in reality this manifestation is accompanied by conscious perception.

The extent to which one can be misled by assuming that the apparent manifestations of pain are reliable signs of such, is rendered plain by Norman's angleworm experiments which any one can repeat with an angleworm, a pair of scissors and a little loose dirt. Who is there that has not seen an angleworm curling up and twisting when part has been stepped on or been chopped by a spade? Norman subjected these "pain contortions" to closer analysis, and found that when an angleworm is cut in two with scissors, the tail end writhes and twists as if in agony, but the head end, the supposed seat of the perception of pain, creeps quietly onward. By cutting each half again in two, the part toward the tail begins to twist and writhe while the part toward the head lies quite still or creeps quietly on. Even the front end of the previously twisting tail part, becomes quiet when it is severed anew, while the rear portion continues twisting. Whatever the explanation of these facts can be, it is most certainly evident that the writhing of an angleworm cannot be regarded as an expression of "pain," because that very end of the body where the higher centers are supposed to be located does not share in the manifestations. Similar but not quite identical phenomena are observed with eels and lizards. If the tail of a lizard is suddenly chopped off, the tail begins to jump about, but the body of the lizard soon lies quiet. Here too we see the apparent expressions of pain in the part of the body where we would least expect it. Such facts show how cautious one must be in the interpretation of the supposed objective expressions of subjective sensations in animals.

Even assuming for the sake of argument that all animals possess varying degrees of conscious perception, this does not answer the question as to whether they feel pain. There are numerous grounds for assuming that, at least in man, pain is a function of his highest psychic powers. It seems to be a general rule that the more intense the response in the form of pain to a given injury, the more highly developed the nervous system responsible for the sensation. The civilized man feels pain where the savage would not notice the irritation. In imbeciles and idiots the sensation of pain seems to be rather vague. Applying these data to the whole animal kingdom, the sensation of pain can be regarded as a psychic supplement to the unconscious reflexes, which has been regularly developed in the animal series in response to injurious influences. Each irritation starts in the nervous system a series of more or less effectual reflexes, movements for flight or defense, or secretion of fluids, as of saliva in the mouth, tears to protect the eyeball, etc. For the behavior of an organ or the whole animal in these circumstances it is immaterial whether these useful reactions are associated or not with a conscious sensation of pain.

Supposing that an animal sticks his paw in a flame. The reflex mechanism from his spinal cord draws the paw back out of the flame, and it is immaterial for the paw whether the animal felt pain thereby or not. But for the further existence of the animal it is of the greatest importance whether he can profit by this experience or not. The next time, warned by the sight of the flame, he may keep cautiously out of the reach of the bite of the flame monster. But learning this lesson presupposes the presence of a number of psychic properties and power of reasoning, recognition, memory, association and deduction. In the absence of all these mental processes the sensation of pain would be of no possible use and quite superfluous. There is thus great probability that the (subjective) perception of pain is a later acquirement than the manifest (objective) reaction to injurious stimuli. It forms a sort of psychic by-product, a by-phenomenon of the automatic reflex. And, as a psychic phenomenon, it is closely connected with the development of the mind.

114 *Residual Nitrogen in the Blood with Surgical Kidney Disease. A. Sabroe.—p. 813.

114. **Residual Nitrogen in the Blood with Surgical Kidney Disease.**—Sabroe remarks that none of the functional tests for the kidneys, with stains, experimental polyuria or determination of the freezing point, have proved unfailingly reliable. They all overlook the vital point that the functioning of the kidneys at a given moment is not necessarily the criterion for their average functional performance. The most reliable information as to the functional capacity of the kidneys seems to be afforded by the urea content of the urine taken from each ureter separately. Positive findings are strong evidence in favor of operability, but the reverse is by no means the case. With surgical tuberculosis, there is always a possibility that the part of the kidney which it is proposed to remove may in reality be the very tissue responsible for the approximately normal functioning. Determination of the residual nitrogen in the blood as a test for the functional capacity of the kidneys, Sabroe declares, is of no clinical value in estimation of surgical kidney affections, as the rise in the residual nitrogen content does not occur until so late in the disease that the clinical findings alone tell the story by that time. This conclusion is based on study of eight patients with tuberculous lesions in the urinary passages, ten with nontuberculous lesions given operative treatment, and eight mixed cases. These twenty-six cases are tabulated with full details, filling thirteen pages, all confirming the disappointing verdict.

Norsk Magazin for Lægevidenskaben, Christiania

116 Nutritional Disturbances in Infants. C. Johannessen.—p. 427.
117 The Normal Peristalsis of the Colon. J. Nicolaysen.—p. 447.
118 Pure Word Blindness. J. Henrichs.—p. 452.
119 *Carbon Monoxid Poisoning in Motor Boats. F. Harbitz.—p. 462.

115. **Chorea.**—Schiøtz concludes from his experience with 211 cases of chorea that it is a neurosis which develops in the predisposed mainly between the eighth and twelfth years in boys, and two or three times as often in girls; usually between the sixth and fourteenth years in girls. There were representatives of all ages under 23 in the total 376 cases tabulated, which includes 165 Danish cases. The inciting causes may be of infectious or toxic nature or emotional stress, but the predisposed age is the period of most active growth. The years closest to puberty are less affected. True chorea has never been observed in animals. The tabulation shows further that the largest number of cases develop in November and the smallest in July. Analysis of 28,754 cases of acute articular rheumatism in Norway, 1907-1913, shows that it affects the sexes about alike. Over 20 per cent. of the cases were in children under 15, consequently we have no ground for calling chorea "childhood's acute articular rheumatism" as some do. Chorea is most prevalent in towns, and among bright, ambitious schoolchildren just at the years when the greatest proportionate demands are being made on the brain and nervous system, and the metabolic processes are particularly lively.

Treatment is like that for neuroses in general, tranquilizing measures with nourishing food and hygiene. The unmistakable benefit from arsenic may be on account of its checking the metabolic processes in general, so that it acts as a sedative. In the pregnant, besides the intensified metabolic processes, there may be an eventual intoxication, conditions thus comparable to the period of most active growth in children. A compilation of 217 cases of pregnancy chorea shows that in 140 of the women it developed in the first half of the pregnancy. In a further compilation of 224 cases of pregnancy chorea, 106, nearly half of the women, were under 21 and 102 between 21 and 26, leaving only sixteen older than this in the total 224 cases. Youth in the pregnant women is thus a predisposing factor to pregnancy chorea. Possibly roentgenoscopy might show in cases of pregnancy chorea that some of the epiphyses have not yet become united to the shafts of the bones, showing that the period of active growth still persists. Infections, autointoxications and emotional stress may be the source of the reflected irritation in the pregnant as well as in children.

119. **Carbon Monoxid Poisoning in Motor Boats.**—Harbitz describes several cases of poisoning from leakage of exhaust gas into the small cabin of a motor boat. In one case a party of four young persons went out on a pleasure trip. Two went into the small cabin and shut the door. In half an hour the others entering found the young man dead and the girl unconscious. The air was close in the room but there was no special odor, no smell of gasoline. The young man was a healthy athlete. He was found stretched out with closed eyes; there was no foam at the mouth and he had not vomited, but had voided excreta. Nothing was found to indicate suicide, and the blood confirmed the assumption of carbon monoxid poisoning. The motor was defective and leaky; the exhaust gas contained unusual amounts of carbon monoxid and the arrangements were such that the exhaust gas might have accumulated in the cabin. Women seem to be more resistant to carbon monoxid than men, and the young woman in this case finally recovered. In a series of 360 cases of coal gas poisoning at Paris, man and wife were affected together in nineteen, and the three survivors were all women. Women in an unconscious condition can hold out longer, as their need for oxygen is less.

Four workmen later had a similar accident. All were fasting, and sought shelter from the cold in the small cabin of the motor boat, 2 by 2 by 1.5 meters in size. All were found unconscious, ice-cold, but not cyanotic; respiration was weak and shallow. Their arms were stiff and pressed tight against the body and the jaws closed tight. Some had vomited and defecated, and the urine flowed spontaneously. Under artificial respiration and massage, heat and stimulants, they were revived in the course of a few hours. Two did not regain consciousness until the next morning. All had headache and nausea and were unable to go to work for a few days, but finally all recuperated. In these motor boats a seat was built in entirely around the edge of the boat and formed a closed space. Leakage of exhaust gas into this space thus permitted it to gain entrance into the cabin. Harbitz calls attention in particular to the stiffness of the body in a seated position in all the four men. It seemed to be an actual rigor mortis in the living body. In the fatal cases of carbon monoxid poisoning, the rigor is generally exceptionally intense. Hultkvist recently noticed signs of carbon monoxid poisoning in himself while waiting in his garage for his automobile engine to heat up. A rat exposed close to the exhaust gas died. He warns further that the dangerous gases from a garage may rise. Harbitz describes further the case of Dr. Kildal, 45 years old, who spent the night on his motor boat. It was a covered boat, with a gasoline engine and a portable heater. The latter was lighted for one hour and later for half an hour. In the morning the engineer felt headache and nausea and found the doctor, stiff and cold beside him, the blood showing carbon monoxid poisoning. Harbitz regards the carbon monoxid in the exhaust gas as responsible for these accidents.

COMPARATIVE RESULTS OF VARIOUS FUNCTIONAL KIDNEY TESTS

BASED ON A SERIES OF CASES *

B. A. THOMAS, M.D.
AND
J. C. BIRDSALL, M.D.
Professor and Associate, respectively, in Genito-Urinary Surgery, Polyclinic Hospital and College for Graduates in Medicine
PHILADELPHIA

So long as the chief cause of death following operations on the genito-urinary tract continues to be uremia, just so long will the concern of the up-to-date conscientious surgeon be the determination of the functional efficiency of the kidneys. Disregard for this important matter too often furnishes the mark of distinction between the skilled urologist and the general surgeon, and explains the relatively high mortality rate for urologic operations in the experience of the general surgeon. Investigation recently[1] revealed the alarming statistics that in twenty-six hospitals in this and neighboring states the mortality for nephrectomy and prostatectomy at the hands of general surgeons was 25.9 and 22.5 per cent., respectively, as contrasted with 7.7 and 4.33 per cent. in seven times the number of operations by eight of the world's most noted urologists. In other words, this means that in a large minority of such operations from 75 to 80 per cent. of deaths are avoidable.

Unfortunately, the urologic world has been almost submerged by a plethora of functional kidney tests — good, bad and indifferent. These are divisible into those of elimination and those of retention, and comprise the forty-five given in Table 1, in the order of their appearance.

It is conceded that the most accurate method of determining the kidney function is a quantitative metabolic study. At the same time it is fully realized that in the vast majority of instances such a procedure is not only impracticable, but not infrequently fallible. Thus the profession has turned to, employed, and discarded one after another of the long list of functional tests; nor is the disputed question yet settled as to which is the best.

In the past it has been the practice of urologists in various parts of the world to employ one or more tests in their particular groups of cases, drawing conclusions as to which was the best. Synchronously or subsequently in another quarter of the globe another investigator has reported his researches, relying on one or more other tests in an entirely different group of cases, but nevertheless asserting the discovery of the most reliable test, irrespective of the fact that he may have had little or no experience with the beloved idol of his professional brother. It may be true that there are several tests equally good. On the other hand, the fact may be that one of the host is truly superior to all the rest, not only as to reliability, but also as to practicability.

It occurred to us that more accurate information relative to the comparative value of the functional tests might be obtained by subjecting each of a group of patients to all of a series of some of the more reliable, and commonly employed, kidney tests. Accordingly, for the past two years, when not inadvisable, we have carried out painstakingly and impartially the following ten functional kidney tests: indigocarmin, phenolsulphonephthalein, the total nonprotein nitrogen of the blood, the urea nitrogen of the blood and urine, the urine urea by the sodium hypobromite method (Doremus-Hinds ureometer), Ambard's ureosecretory constant of the blood and urine, the creatinin of the blood, and the cryoscopy of the blood and urine.

TABLE 1.—FUNCTIONAL KIDNEY TESTS

TESTS OF ELIMINATION

Total quantity of urine.
Odor after asparagus (1820)
Odor after turpentine (1820)
Opium (1857)
Mercury (1865)
Iodid of ethyl (1867)
Potassium iodid (1867)
Potassium bromid (1867)
Indigo (1867)
Anilin (1867)
Turmeric (1867)
Alkaline carbonates (1867)
Fuchsin (1877)
Quinin sulphate (1877)
Salicylic acid (1877)
Benzoic (hippuric) acid (1879)
Methylene blue (1897)
Rosanilin (1898)
Phlorizin (1899)
Indigocarmin (1903)
Experimental polyuria (1904)
Diastase (1908)
Phenolsulphonephthalein (1910)
Pepsin (1912)
Uranin (sodium fluorescein) (1913)
Lactose (1913)
Trypanblue (1914)

TESTS OF RETENTION

Total urinary solids
Normal urinary salts (alkaline chlorids, phosphates and sulphates, and alkaline earths) (excretion)
Urine urea (excretion) (1872)
Total nitrogen (1883)
Cryoscopy (blood, urine) hemorenal index (1898)
Electrical conductivity (blood, urine) hemorenal index (1900-1904)
Wright's excretory quotient (1904)
Chlorids (blood, urine) hemorenal index (1907)
Urea nitrogen (blood, urine) (1908)
Ambard's constant (ureosecretory index) (1910)
Urinary toxicity (1910)
Acidosis (1910)
Blood nonprotein nitrogen (1912)
Creatinin (1914)
Creatin (1914)
Uric acid (1914)
Indican (1914)
Phosphates (1916)

These ten tests have been selected for study from the extensive list, chiefly because several of them are routine methods and are believed to be the most reliable and practical. A number of others, namely, phlorizin, potassium iodid and lactose, experimental

polyuria, acidosis and chlorids, might have been included, but would probably not have proved more meritorious than those utilized, and would merely have imposed an additional inexcusable ordeal for the patients. Phlorizin has few adherents today. Whether or not the test is too sensitive, grave fallacies or inconsistencies have arisen in the study of both normal and diseased kidneys, rendering the test undependable in the experience of most investigators. Potassium iodid and lactose in conjunction with salt and water possess mainly a clinical interest, and have been utilized for the differentiation of tubular and glomerular nephritis. This is a matter which interests internists rather than surgeons. Moreover, the method lacks universal confirmation. The experimental polyuria test of Albarran has much to recommend it, but is open to the following objections: (1) difficulties with ureteral catheters and accurate collections of the respective urines; (2) unilateral reflex stimulation or inhibition of function, incident to catheterization; (3) the fact that two or three hours is an unjustifiably long time to permit the ureteral catheter to remain in situ; (4) the inability of some patients to drink the required amount of water; (5) occasionally, the failure to produce polyuria by increased water intake, and (6) in slight lesions of the kidneys the inability to detect differences between the two sides. Acidosis and the phosphate and chlorid content of the blood are estimations promissory of much value in nephritis, but as yet possess only clinical and research importance.

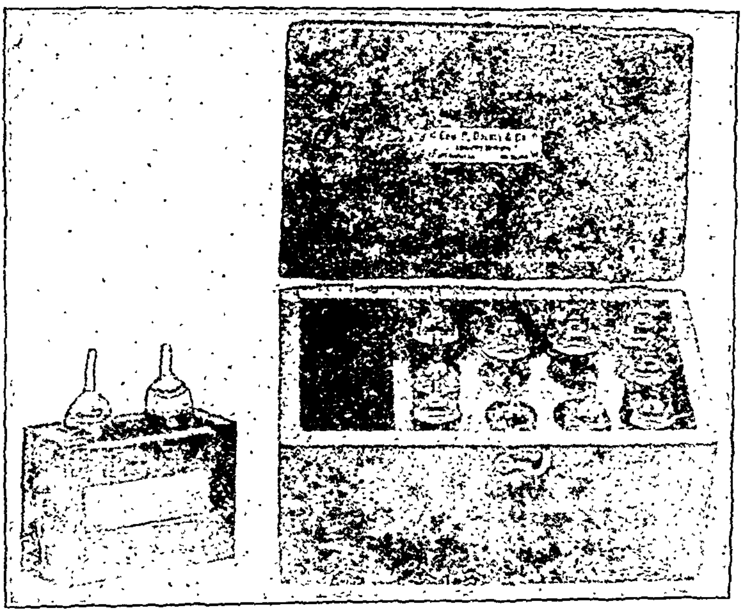

Fig. 1.—Colorimeter for the quantitative determination of indigocarmin.

TECHNIC EMPLOYED IN TESTS

Indigocarmin.—In the cases furnishing the text of this report, in order to parallel the method of employment of phenolsulphonephthalein, indigocarmin was administered intramuscularly,[2] although for years in many cases we have injected the dye intravenously and now prefer this method for chromo-ureteroscopy in the unilateral determination of kidney function. The quantitative determinations were made for three hourly intervals, the Duboscq[3] or a recently improvised less expensive colorimeter (Fig. 1) being utilized. Due consideration was accorded the onset of elimination and the quantitative output, although greatest reliance was placed on the index of elimination,[4] that is, the ratio of output for the first and third hours, respectively, taking into consideration the onset and alternative interval quantitative output, and hence the stability of kidney function.

Phenolsulphonephthalein.—The application of this test varied from that stipulated by Rowntree and Geraghty[5] in the following respects: The quantitative output was computed for three instead of two hours, and the elimination for the first hour was measured from the time the drug was administered, not from the time it first appeared. It has frequently happened that twenty minutes, a half hour, or even an hour or more, has elapsed following the injection of phenolsulphonephthalein before its appearance in the urine. It has therefore seemed more rational, scientific and accurate to regard the quantitative output for the first hour from the time the drug was administered; otherwise the quantity commonly regarded as eliminated for the first hour comprises that for the hour after elimination begins, plus the time required for it to appear. The latter is a wide variable in renal disease, and, we believe, should not be disregarded.

Determination of Nonprotein Nitrogen of the Blood.—The method employed for the estimation of the nonprotein nitrogen of the blood is in general that followed by Folin and Denis.[6]

> Ten c.c. of blood are withdrawn from a vein and placed in a 100 c.c. volumetric flask containing about 5 drops of a 20 per cent. solution of potassium oxalate. The flask is immediately shaken and filled up to the 100 c.c. mark with methyl alcohol — acetone free. The flask is vigorously shaken and allowed to stand, tightly stoppered, for at least two hours. The fluid is then separated from the coagulum by filtering. From 2 to 3 drops of a saturated alcoholic solution of zinc chlorid are now added to the filtrate, and after a few minutes the mixture is again filtered.
>
> Ten c.c. of the alcoholic filtrate, which are the equivalent of 1 c.c. of blood, are pipetted into each of two thin glass test tubes, about 200 mm. in length and 25 mm. in diameter. Four-tenths gm. of potassium sulphate, 1 drop of a 10 per cent. copper sulphate solution and 1 c.c. of concentrated sulphuric acid—all reagents to be of highest purity—are added to each tube in the foregoing order. The test tubes are then placed in convenient holders and heated over small microburner gas flames until the mixture becomes completely colorless. As soon as the test tubes have become cool, 8 c.c. of distilled water are added.

Aeration of the ammonia is carried out in the following way:

> Into each of two 500 c.c. Erlenmeyer flasks are placed 200 c.c. of distilled water., 10 c.c. of fiftieth-normal sulphuric acid and a few drops of the indicator—Congo red. Each flask is now closed with a two-hole stopper having a Folin tube passing nearly to the bottom of the flask.
>
> The apparatus is now adjusted (Fig. 2) in the following order: Woulfe bottle; Flask C, Test Tube D, containing the

digested mixture, and the acid wash bottle. Between Test Tube D and the acid wash bottle, Flask C′ and Test Tube D′ are placed as a control. A sufficient quantity of a saturated solution of sodium hydroxid is added to Test Tubes D and D′ until a bluish color appears.

By means of suction, air is made to pass through the apparatus slowly at first and then rapidly for from twenty to twenty-five minutes. The apparatus is then disconnected and the contents of Flasks C and C′ are titrated against fiftieth-normal sodium hydroxid and the estimation of nonprotein nitrogen is made. One c.c. of fiftieth-normal sulphuric acid is neutralized by 0.00028 gm. of nonprotein nitrogen.

Determination of Urea in Urine.—For rapid determination of the amount of urea in the urine, we have made use of the hypobromite method.

The apparatus, Doremus' ureometer, consists of a graduated fermentation tube mounted on a glass foot and graduated arm with glass stopcock for the introduction of urine.

First, urine should be introduced into the graduated arm and the glass stopcock closed, the opening being full of urine. The graduated fermentation tube should then be rinsed free from all traces of urine and the graduated arm filled with urine to the 0 mark. The graduated fermentation tube should now be filled with hypobromite solution.[7] By means of the glass stopcock, 1 c.c. of urine is permitted to flow slowly into the graduated fermentation tube. The urine will rise through the hypobromite, and the urea will instantly decompose, giving off nitrogen gas. The ureometer indicates either the milligrams of urea in 1 c.c. of urine or the grams of urea per fluidounce of urine.

A twenty-four hour specimen should be collected and mixed, and a specimen of this taken for the test if accurate data are to be had.

Determination of Urea Nitrogen of Blood and Urine.—We use the following method:

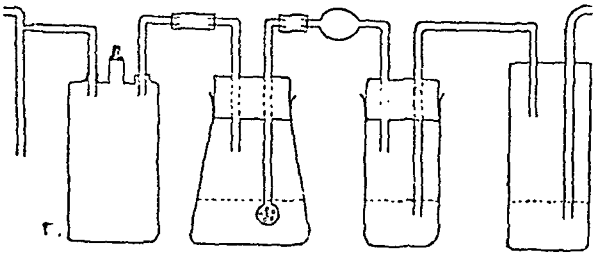

Fig. 2.—Arrangement of apparatus for aeration in nitrogen determination.

Three c.c. of blood are introduced into each of two test tubes of dimensions similar to those employed for the nonprotein nitrogen determination. From 2 to 3 drops of 20 per cent. solution of potassium oxalate are added. The mixture is well shaken and 3 c.c. (of a 0.6 per cent. solution) of acid potassium phosphite, one urease tablet,[8] which has been previously pulverized, and about 5 to 10 drops of amylic alcohol, the latter to prevent foaming in the aeration process, and then 5 c.c. of distilled water are added. The same apparatus as employed for the nonprotein nitrogen is used, and with the test tubes immersed to the level of the contained mixture, in beakers of water at 50 C., aeration is carried out for from two to three minutes. At the end of this time from 3 to 5 gm. of potassium carbonate are added to each test tube, and aeration is continued for fifteen minutes. In estimating urea nitrogen of the urine, 0.5 c.c. of urine should be used and the same technic employed as described above.

The final estimation is made by titrating the contents of the flask against fiftieth-normal sodium hydroxid, and the computation is made in the same way as for nonprotein nitrogen.

Creatinin of the Blood.—In the estimation of the creatinin of the blood we have used the Duboscq colorimeter and the following application of Folin's method:

To 6 c.c. of blood in a graduated 50 c.c. centrifuge tube, 5 drops of a 20 per cent. solution of potassium oxalate and enough distilled water to bring the mixture up to the 30 c.c. mark are added. The mixture is then stirred until the red blood corpuscles have become laked. Then 1 gm. of picric acid is added and the mixture again stirred at intervals with a glass rod until it becomes a light yellow. The tube is then centrifuged and the supernatant fluid filtered. To 10 c.c. of the filtrate is added 0.5 c.c. of 10 per cent. sodium hydroxid, and a similar amount of 10 per cent. sodium hydroxid is added to 1. c.c. of standard creatinin in saturated picric acid. The reading is then made by means of the Duboscq colorimeter exactly at the end of ten minutes after the addition of the sodium hydroxid.

The creatinin standard solution is made up after the method of Benedict:[9] fifteen mg. of creatinin are dissolved in 15 c.c. of tenth-normal hydrochloric acid, and 1 c.c. of the mixture is diluted up to the 100 c.c. mark with saturated picric acid solution. Ten c.c. contain 1.5 mg. of creatinin.

Estimation of the Ambard Quotient.—Ambard's quotient, or the ureosecretory constant, resulted from a series of studies[10] of the laws governing the concentration of urea in urine.

Ambard's First Law: By experimentation Ambard found[11] that if the kidney excreted urine which maintained a constant urea concentration, its urea output during any given time varies as the square of the concentration of urea in the blood of any given person.

C = grams of urea per liter of urine.
Ur = grams of urea per liter of blood.
V = amount of urine excreted in twenty-four hours.
Vxc = urea output in twenty-four hours.
Constant $= \frac{Ur}{\sqrt{c}}$ provided the urine has a constant concentration.

Ambard's Second Law: By further study[12] Ambard found that variations in the concentration of the urea in the urine altered the relation between the rate of urea excretion and the urea concentration of the blood. After many examinations Ambard concluded (second law) that when a urine of variable concentration is excreted, if the blood urea remains at a constant concentration, the urea output for any given time will be inversely proportional to the square root of the urea concentration in the urine. Twenty-five gm. of urea per liter D_{25} was adopted as the standard concentration of urea in urine. D_{25} equals $\frac{D \times \sqrt{c}}{5}$.

Ambard's third law states that when the urea concentration of the blood and of the urine varies in direct proportion to the square of the urea concentration in the blood and in inverse proportion to the square root of the urea concentration in the urine, the ureosecretory constant $= \frac{Ur}{\frac{D \times \sqrt{c}}{5}}$ or $\frac{Ur}{D}$.

Estimation of Ambard's constant in a case of prostatic hypertrophy[25]:

Amount of urine collected for one hour = 60 c.c.; $V = 60 \times 24 = 1{,}440$ c.c. — urea per centimeter in urine = 20 per liter. Urea output in urine = 1,440 × 20 per cent. = 28.80 (D).

---

[7] The hypobromite is prepared as follows: One hundred gm. of sodium hydroxid are dissolved in 250 c.c. of distilled water. To 20 c.c. of sodium hydroxid solution, in a 50 c.c. graduated cylinder, 2 c.c. of bromid are added; this is shaken and enough distilled water is added to bring the mixture up to the 44 c.c. mark. This makes the hypobromite solution, and as it does not keep well it should be made up fresh each day.

[8] The soy bean urease tablets are put up in this convenient form by the Arlington Chemical Company, Yonkers, N. Y. Each tablet contains sufficient enzyme for a single test.

[9] Benedict: Jour. Biol. Chem., 1914, **18**, 183.

[10] Ambard: Étude sur les concentrations urinaires, Arch. internat. de physiol., 1909, **8**, 437.

[11] Ambard: Rapports entre le taux de l'urée dans le sang et l'élimination de l'urée dans l'urine, Comp. rend. Soc. de biol., 1910, **69**, 411.

[12] Ambard: Rapports de la quantité et du taux de l'urée dans l'urine, la concentration de l'urée du sang étant constante, Compt. rend. Soc. de biol., 1910, **69**, 506.

This amount corrected for concentration of 25 per cent. = $28.80 \times \frac{\sqrt{20}}{5} = 28.80 \times 0.88 = 25.34$—.

Urea estimation of the blood = 0.514 gm. per liter.

$$\text{Ambard's constant} = \frac{Ur}{\sqrt{D_{25}}} = \frac{0.514}{\sqrt{25.34}} = \frac{0.514}{5} = 0.1.$$

The normal constant has been found to vary between 0.06 and 0.08.

Cryoscopy.—The Beckmann cryoscope, necessitating the preliminary determination each time of the lowering of the freezing-point of distilled water, was employed. The details of cryoscopy need not be given, since in our experience the δ blood and the Δ of the urine have been of all the tests the least reliable. Aside from comparative tests on the urines from each kidney separately, cryoscopy, as a test of kidney efficiency, is of minimal value.

COMPARATIVE RESULTS OF TESTS

In order better to display the comparative results of these various functional kidney tests, they have been tabulated in a number of exemplary cases, normal and pathologic, the latter including mostly retention of urine, due to prostatic or vesical orifice obstruction, or to urethral stricture, with a few nephritics and other renal diseases, mainly surgical.

In Table 2, we enumerate a few absolutely normal ambulatory patients who have been subjected to two or more of the functional tests. The number of cases is small, but we believe sufficient to permit judgment as to the results for the functional tests studied. For indigocarmin this was found to be from five to twelve minutes[13] for onset of elimination; from 18.45 to 24.5 per cent. for quantitative output for three hours, with an index of elimination of from 2.9 to 6.7. For phenolsulphonephthalein the respective figures were nine to fourteen minutes, 38.19 to 77.99 per cent. and 1.6 to 16.1. It will be observed that phenolsulphonephthalein was not eliminated as early as indigo, that there was greater variability in quantitative output and extreme variability as to index of elimination, the substance apparently not lending itself well to this method of determination, at least for hourly periods. In this connection the recent animal experimental work of Kendall[14] is of paramount importance. He finds that the phenolsulphonephthalein output is, fundamentally, the ratio between its rate of reduction and the supply of oxygen in the body, and in any given case is dependent on so many factors that its localization effects in any one organ are impossible. If this work is substantial clinically, it will explain many of the singular results heretofore obtained from the employment of this drug as a functional kidney test.

In normal persons the total noncoagulable nitrogen of the blood varied from 25 to 31 mg., and the blood urea nitrogen from 10 to 15 mg. per hundred c.c. The urine urea nitrogen, on the other hand, varied from 58 to 210 mg. per hundred c.c., and in our experience presented nothing of value over the Doremus ureometer method with sodium hypobromite, in which the findings were from 9 to 17 mg. per cubic centimeter. Correspondingly, the ureosecretory index of Ambard showed results of from 0.03 to 0.09. It will be observed that of the retention tests employed, the noncoagulable nitrogen and the urea nitrogen of the blood showed the greatest uniformity of results and ran a close parallelism. Our results, therefore, do not support the contention of Smith[15] that Ambard's constant or McLean's modification is a more reliable index as to renal involvement and prognosis than is the determination of the blood urea nitrogen alone. It has been maintained by Addis and Watanabe[16] that certain functional tests—as phenolsulphonephthalein—fail to reveal the latent deficiencies in the kidney function, whereas experimental urea may suffice to do this.

We have invariably obtained high figures for creatinin in normal persons, namely, from 3.2 to 4.82 mg. per hundred c.c. of blood. This has been a great disappointment in view of the definite normal and abnormal values and emphatic diagnostic and prognostic claims stipulated by Myers and Lough.[17]

The normal values for cryoscopy have been so variable, namely, from —0.45 to —0.51 degrees for δ and —0.59 to —1.39 degrees for Δ that we have been unable to place much reliance on the results. Therefore, compared with simpler tests, even with respect to the separately catheterized urines of each kidney, in comparison with the molecular concentration of the blood, cryoscopy of the total urine or of the blood alone is, or should be, obsolete. Factors, such as water, diet, polyuria and anemia, materially affect the cryoscopic determinations which, associated with the technical disadvantages, render the method useless.

The pathologic cases subjected to a comparative study of the various functional tests are presented in Tables 3, 4 and 5. Table 3 consists of cases of retention of urine. Of the seventeen cases studied, eleven were due to prostatic hypertrophy, three to prostatitis and seminal vesiculitis, and one each to obstructive contracture of the sphincter vesicae, stricture and carcinoma of the prostate. In all cases operation was successfully performed save in Cases 15 and 16, and organic disease contraindicated surgical intervention in these two cases. The first patient died in a few days of pyelonephritis, and the second case was so complicated by hypertension, myocarditis and dilatation that the patient died a month later. A review of this table reveals the following notable features: The onset of elimination of indigocarmin was noted in from eight to 100 minutes, while phenolsulphonephthalein appeared in the urine in from nine to ninety minutes. In five patients indigo, and in two patients phenolsulphonephthalein, did not appear for an hour or more after injection. Thus we emphasize that this period is not negligible in the quantitative estimation of either of these substances, so far as the first hour's output is concerned, and insist for the best and most reliable data relative to kidney function, that the quantity for the first hour should be timed from the moment of injection rather than from the onset of its elimination. The quantities eliminated for three hours varied from 2.53 to 34.33 per cent. for indigo and from 5.85 to 90.09 per cent. for phenolsulphonephthalein. The indexes of elimination of the two substances suggest a parallelism, but the results have not been so reliable in the case of phenolsulphonephthalein as with indigo. The index of indigo elimination has been extraordinarily trustworthy, and as a guide to kidney efficiency and operability has proved itself *par excellence,* the best at our command. Almost exclusive reliance on the index as an indication of the stability of kidney function in cases of prostatic hypertrophy during the last three years has been rewarded with recovery in every case of prostatectomy. In Case 3, in spite of an indigo index of 0 three weeks before a minor operation, the patient recovered. It will be observed, however, that the index for phenolsulphonephthalein immediately before operation was in the positive phase and the repetition of the indigo test was thought to be unnecessary. Case 15 showed the indexes for both indigo and phenolsulphonephthalein in the negative phase. Operation was not to be considered, and the patient died in a few days. Case 16 illustrates well the fact that the renal function is not the only consideration relative to operability. The patient was the victim of marked myocarditis with dilatation and hypertension, and died a month after his examination.

[17] Myers, V. C., and Lough, W. G.: The Creatinin of the Blood in Nephritis: Its Diagnostic Value, Arch. Int. Med., October, 1915, pp. 536-546.

The total noncoagulable nitrogen varied from 22 to 106 mg. In eleven of the thirteen successful prostatectomies shown in this table, the nonprotein nitrogen exceeded the normal values found in Table 2, and in the cases of the patients who died from a few days to a few weeks after the functional tests were performed, the values for nonprotein nitrogen were no higher than in the cases of several of the patients successfully operated on.

The findings for blood urea nitrogen ranged from 8 to 74 mg. and closely paralleled the results of noncoagulable nitrogen.

The urine urea nitrogen results varied from 20 to 360 mg. per hundred c.c. and permit of no deductions of value; indeed, in comparison with the simple Doremus method, with findings from 2 to 30 mg. per cubic centimeter, the advantage is strongly in favor of the latter, although it is universally admitted that the sodium hypobromite method is susceptible of erroneous results.

It was hoped that Ambard's constant or quotient might furnish a more reliable index of renal efficiency than either the blood or urine urea separately. Unfortunately, this has not been true. In six of thirteen patients successfully operated on, the ureosecretory index was so high that operative intervention might be said to have been contraindicated. We agree, therefore with Jonas and Austin[18] and question whether the original formula[19] or McLean's[20] modification is truly the expression of the physiologic law underlying the relation between the urea concentration of the blood and urine and the rate of urea excretion.

Our results with creatinin have varied from 2.2 to 5.5 per hundred c.c. of blood. In a number of the patients successfully operated on the findings were higher than in a few patients who died shortly after the determinations.

The cryoscopic readings varied for the blood from —0.38 to —0.57 degrees; for the urine from —0.16 to —1.45 degrees. The results were such as to stamp this method as worthless so far as the proper treatment of such cases as are shown in Table 3 is concerned.

Table 4 comprises eight cases of nephritis — two of acute parenchymatous, three of chronic parenchymatous, two of chronic interstitial and one of chronic diffuse — studied with respect to the several functional renal tests. It will be noted that in the cases of acute and chronic parenchymatous nephritis, the quantitative output of both indigo and phenolsulphonephthalein was high, and also that almost without exception the indexes of elimination were in the positive phase. Contrasted with this it will be observed that in the chronic interstitial type of the disease, although the quantity eliminated for three hours was variable, the indexes of elimination were constantly in the negative phase. The noncoagulable blood and the urea nitrogen range from 42 to 98 mg. and from 14 to 25 mg., respectively. The urine urea determinations per hundred c.c. with urease or by the Doremus method were so variable as to be valueless. However, it is significant to note that the Ambard quotient in the cases of parenchymatous nephritis was uniformly high, above the normal, while in the cases of chronic interstitial and diffuse nephritis it was constantly low, below the normal. Apparently, this method may be utilized for the differentiation of parenchymatous and interstitial nephritis, and would seem to be more valuable in this respect than the determination of blood urea nitrogen or total nonprotein nitrogen alone, although as a matter of fact it furnishes no more information than is supplied by the index of elimination of indigocarmin or possibly phenolsulphonephthalein.

The values for creatinin vary from 3.21 to 5.4 mg., and are uniformly high. Improvement has occurred, since the determinations, in the general health of all patients, excepting Patient 4, who died recently.

The results of cryoscopy both of the blood and of the urine present nothing noteworthy, and may be disregarded in a study of nephritides.

In Table 5 we present eighteen pathologic cases, mostly prostatics studied only with indigocarmin and phenolsulphonephthalein, and although the findings demonstrate nothing not already shown in the previous tables, we believe the results to be of sufficient interest to warrant consideration, in view of the popular but unfounded preference for phenolsulphonephthalein as a functional kidney test. It will be observed that the parallelism existing between the results of the two substances is most striking, particularly with respect to the indexes of elimination. Discrepancies exist in only four instances, namely, Cases 3, 8, 11 and 15, and in the last the negative index for indigo was known to be due to improper collection of the hourly specimens of urine. For similar reasons, fallacious indexes for both indigo and phenolsulphonephthalein were obtained in Cases 12 and 17. In Case 3, the failure of phenolsulphonephthalein to appear for two hours after injection is inexplicable, unless the recent experimental work of Kendall is substantiated. In Cases 8 and 11 the disagreement between the indexes for indigo and phenolsulphonephthalein on the one hand, and the clinical conditions and subsequent states of the patients, on the other hand, furnishes further support to the belief that phenolsulphonephthalein does not lend itself so well as indigo to this method of determination. Finally, attention is called to Cases 6 and 11 in support of former assertions to the effect that the index of elimination of indigocarmin is a truer gage of renal function of a person than is merely the quantitative output for two hours, particularly if this hourly estimation ignores the period from the time of injection until the substance appears in the urine. In Cases 9 and 10, in which death followed prostatectomy, it is worthy of note that the indexes for both indigo and phenolsulphonephthalein were in the negative phase and contraindicated operation, in spite of the relative satisfactory quantitative outputs for the respective substances.

CONCLUSIONS

1. The analysis of the results of the several functional kidney tests employed in this study emphasizes our belief that of those utilized none possessed virtues superior to indigocarmin, not excepting the tests of retention.

2. Indigocarmin, in our experience, has been more trustworthy and practical than phenolsulphonephthalein.

3. In cases which may require an additional functional test for confirmatory judgment, phenolsulphonephthalein, total nonprotein nitrogen or urea nitrogen of the blood may be utilized.

4. Ambard's quotient was of questionable utility so far as the differentiation of nephritis is concerned, and possessed no actual advantage over indigo or phenolsulphonephthalein.

5. Cryoscopy of the whole blood and urine is valueless. If unilateral values are desired, ureteral catheterization is necessary and may be obviated by recourse to more modern and practical tests.

6. Creatinin of the blood and urine urea nitrogen either per hundred c.c. by the urease or by Doremus' sodium hypobromite method demonstrate results so variable as to be unreliable.

7. Irrespective of the finer medical aspects of renal function, the differentiation of glomerular and tubular nephritis, the detection of renal disease in its incipiency, etc., the best functional kidney test today is indigocarmin, at least for the surgeon, because it is not only the most practical test, but it is unsurpassed in reliability, whether employed for unilateral determination by the method of chromo-ureteroscopy or for total function through reliance chiefly on the index of elimination.[21]

[21] The remaining article of this symposium, by Drs. Krotoszyner and Stevens, and the discussion will appear next week.

Occupational Training for the War Cripple.—It is the general consensus of experience that the decision by the man to undertake a course of training must be a voluntary one. Of course, he may be retained in the military organization and detailed to trade classes in the same way as he is detailed to guard duty, but this would not make for successful results. The unwilling and rebellious pupil learns but little, the earnest and ambitious one makes rapid progress. The man must be persuaded, therefore, to take up instruction; the future advantages of being a trained workman in some skilled trade should be pointed out, and the practical arrangements to be made for him during the course of instruction carefully explained. There is no royal road to success in this effort, but after gaining the soldiers's friendship and confidence, a patient persistence will win the battle. If a competent visitor has been in touch with the man's family during his absence at the front, the members of the home circle can be easily convinced of the wisdom of his reeducation; this will make all the simpler persuasion of the man himself.—Douglas C. McMurtrie: The War Cripple, Columbia War Papers.

RECURRENCE AFTER OPERATIONS ON THE BILIARY PASSAGES *

DANIEL N. EISENDRATH, A.B., M.D.
CHICAGO

One of the reasons for the rapid growth of many a modern commercial enterprise is the exchange of experience at frequent cabinet meetings of the heads of departments, as to the cause for success or failure in their respective spheres of activity. We can profit by following such a method because the time has arrived when a discussion of the reasons why a certain percentage of our operations on the biliary passages is not successful is necessary. It is to this group of recurrence cases that we must devote our investigative energy in order to lessen their number. Statistics are of little value as to the percentages of satisfactory and unsatisfactory results unless practically all of the patients operated on have been actually examined at intervals for a number of years by the surgeon himself, and this is rarely possible. Recurrences may take place, as I shall presently show, many years after the original operation, and the patient may have been operated on by another surgeon long after the first operator considered the case as cured. A far more valuable contribution, it appears to me, would be for each one of us to report in the future, as Deaver[1] has recently done, the recurrence cases in which we have either actually operated or otherwise diagnosed. In this way the cases in which we have operated primarily can be studied, and a profitable discussion will result as to the causes of our failures.

My object is to follow out such a plan, and after a review of our present knowledge of the varieties of recurrences, to report a series of personal observations and suggestions as to their possible avoidance in the future.

DIVISION OF RECURRENCES

The most convenient classification of recurrences is into true and false. By true recurrences, we mean that an actual reformation of calculi has taken place as the result of the persistence or the recrudescence of a former infection.

TRUE RECURRENCES

In the early history of gallbladder surgery, reformation of calculi around foreign bodies like silk sutures was observed. Floercken[2] has collected eight instances of this form of true recurrence, but at the present time this need not be considered.

The question as to whether calculi can reform in the gallbladder has been greatly cleared up by the work of Aschoff and Bacmeister[3] which has been confirmed by Ehrhardt.[4] They found that the so-called glands of Luschka are in reality clefts in the wall of the gallbladder lined by epithelium. In the normal viscus they do not penetrate beyond the muscular coat; but in pathologic gallbladders they are found to extend to the serous coat, are greatly dilated, are filled with the products of inflammation, and are the cause of reinfection after cholecystostomy. At times, cholesterin calculi in the process of formation have been found in these crypts or glands of Luschka (Fig. 1), and thus one can readily explain the reformation of calculi after cholecystostomy by the extrusion of these minute calculi into the lumen of the gallbladder, thus serving as a nucleus for the formation of larger calculi.

[4] Ehrhardt: Arch. f. klin. Chir., 1907, **83**, 118.

Whether or not true reformation of calculi takes place in the common or hepatic ducts is at present an open question. The subject of intrahepatic cholelithiasis is a comparatively new one. Although Cruvelhier[5] in his atlas has an excellent illustration of this condition, the subject did not attract much attention until the appearance of the article by Beer,[6] who found it in six of seventy-two cholelithiasis cases (8.3 per cent.) at necropsy. In five of these, there were also common duct stones present, and in one they were present, in addition, in the gallbladder. Courvoisier[7] in 1890 had collected fifty instances, and Körte,[8] in 1889, said it might play an important part in prognosis after gallbladder operations. Lewisohn,[9] Jenckel,[10] Riese,[11] Quénu,[12] Deaver,[12] Kehr,[13] and I[14] have since observed the condition clinically. In one of my own cases this intrahepatic cholelithiasis was undoubtedly the cause of a recurrence (Fig. 4 of former article).

Taking all of these observations into consideration, we are justified in saying that a true reformation of calculi can occur in the gallbladder; a number of apparently authentic cases of this kind have been reported by Stanton[15] and others. In regard to the true reformation of calculi in the common or hepatic ducts after removal of the gallbladder, there is much doubt. Cases in which calculi are found in these ducts at secondary operations even after previous drainage and removal of calculi[16] are in all probability due to the descent of calculi from the intrahepatic bile passages, a fact which must be borne in mind in our prognosis of common or hepatic duct cases even when no calculi were found at the first operation.

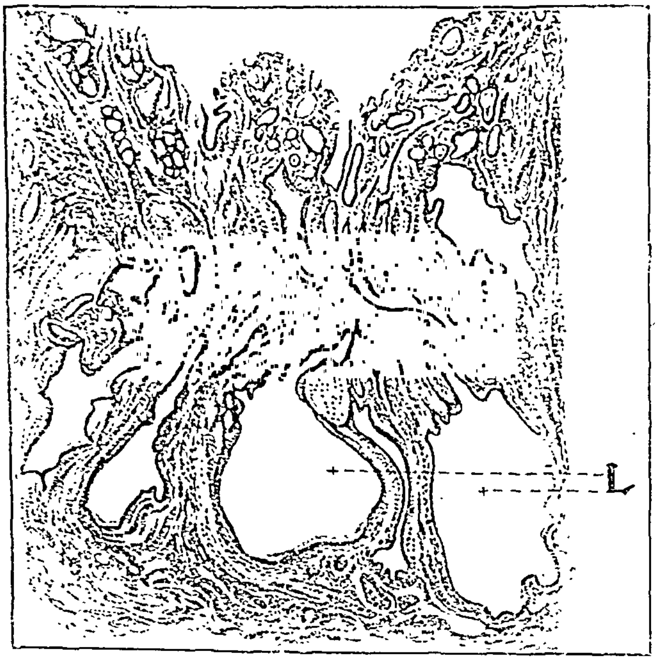

Fig. 1.—Section of gallbladder wall in case of chronic cholecystitis showing dilated crypts of Luschka (*L*) (Aschoff) which are the source of reinfection.

FALSE RECURRENCES

Under false recurrences I include: (1) overlooked calculi; (2) adhesions; (3) chronic pancreatitis; (4) persistence or recurrence of original infection; (5) strictures; (6) fistulas (internal or external); (7) faulty technic, for example, suturing gallbladder to the abdominal wall or insufficient removal of cystic duct, permitting the formation of a dilated stump,[17] with possible true reformation of a calculus in same; (8) incorrect diagnosis, for example, tabes and spinal tumors; (9) coexistence of two conditions, for example, ureteral calculus (see my own recurrence cases); (10) contraction of the ampulla of Vater, and (11) cancer of head of pancreas.

Persistence of infection, overlooked calculi and chronic pancreatitis constitute the majority of all causes of recurrence in my own experience, as well as in that of others who have written on this subject. Time will not permit of detailed consideration, but I have been more and more impressed with the fact, as my experience increases, that no surgeon who does not possess a thorough knowledge of the pathology of infection in the biliary tract can hope to progress in this field. The period has passed during which a surgeon who possesses only sufficient technical knowledge to drain or even to remove a gallbladder should operate in these cases.

PERSISTENCE OR RECURRENCES OF INFECTION

The fact that the calculi[18] are the result and not the cause of the infection is not so generally understood as it deserves to be. It is beyond the province of this paper to discuss the indications for cholecystectomy, but microscopic examination of the gallbladder after removal, in cases of persistence or recurrence of infection, clearly demonstrates the fact that every attack causes serious changes in the normal contractility and elasticity of the gallbladder which favor stagnation and provide ideal conditions for reinfection. The studies of Aschoff and others on thousands of gallbladders removed at operations clearly demonstrated the fact that the recurrence of persistence symptoms is due to the retention of infected secretion in the crypts of Luschka (Fig. 1), or even reformation of cholesterin calculi in them. Again, in many cases it is impossible to remove all of the crystalline detritus which we so often find on opening the gallbladder,[19] and if infection persists it is easy to see how recurrences can take place.

[14] Eisendrath, D. N.: Overlooked Common Duct Stones, The Journal A. M. A., March 31, 1917, p. 968.

[15] Stanton (Ann. Surg., 1915, **61**, 226) reports one case of his own and has collected all of the published instances except those of Deaver (Surg., Gynec. and Obst., 1913, **17**, 667), who removed 100 calculi from the gallbladder and two years later 200 more. Kehr has seen true reformation only three times in 2,000 operations. Under recurrence cases, I report several examples of apparently true reformations.

[16] One can easily overlook common duct calculi at the *first* operation, especially if any small calculi were present. The escape of these through the T-tube is one of the great advantages of common duct drainage.

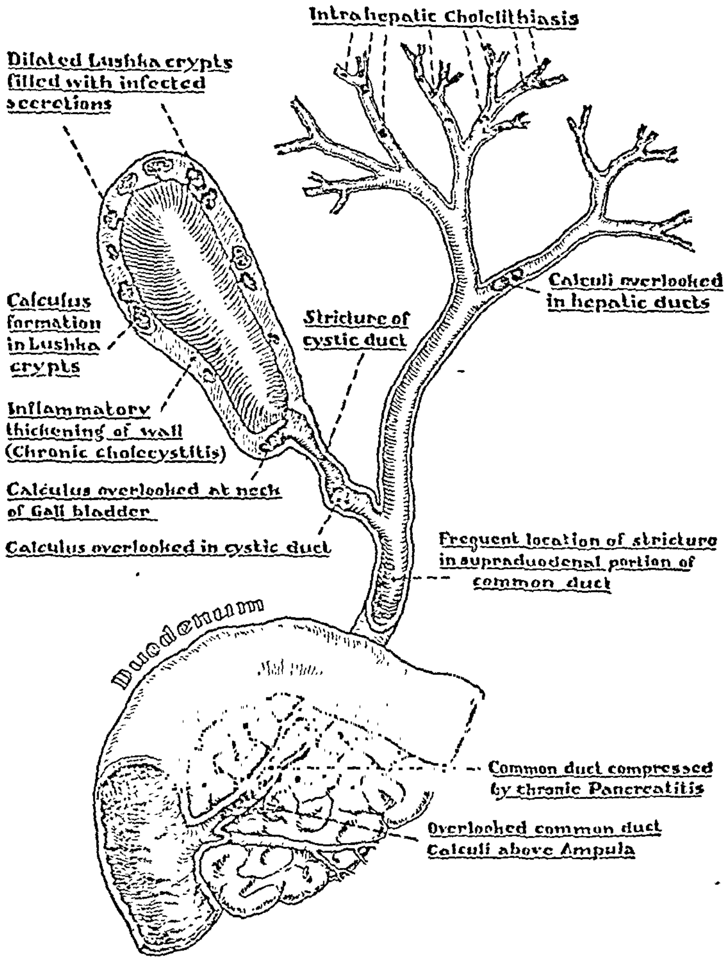
[17] Floercken (Deutsch. Ztschr. f. Chir., 1912, **113**, 604) found a dilatation of the cystic duct the size of a plum three years after cholecystectomy, and a brown calculus embedded in the wall of the dilatation and none elsewhere. In one of my cases (Case 657 of recurrences) two years after operation the cystic duct formed a pseudogallbladder 1 inch long, the size of an almond, containing a calculus the size of a millet seed (Fig. 2). Von Haberer and Clairmont (Arch. f. klin. Chir., 1904, **73**, 697) confirmed the work of deVoogt (Nederl. Tijdschr. v. Geneesk., 1898, **43**, 236), and Oddi (Centralbl. f. Chir., 1889, No. 8) found that a dilatation of the cystic duct stump followed removal of the gallbladder in dogs (Fig. 2).

[18] Naunyn was of the opinion that stagnation alone sufficed to explain the origin of gallstones, but Aschoff and every one else who has investigated the subject believes that infection is essential. Aschoff believes that aseptic cholesterin calculi may be present in the gallbladder for a long time, but that as soon as infection supervenes, the so-called secondary calculi are formed.

The question of recurrence of infection symptoms after common duct operations, even without the presence of calculi, is one that deserves further study in the near future, and must be borne in mind when one is making a prognosis after common duct operations.

OVERLOOKED CALCULI

Any one familiar with anatomy can readily understand how it is possible to overlook small calculi which lie beneath a fold of mucous membrane at the neck of the gallbladder or within one of the pocket-like tortuosities of the cystic duct (Fig. 2). I have frequently found such calculi in the examination of the specimen (after removal of the gallbladder and cystic duct) which I feel confident would have been overlooked.



Intrahepatic Cholelithiasis
Dilated Lushka crypts filled with infected secretions
Calculus formation in Lushka crypts
Stricture of cystic duct
Calculi overlooked in hepatic ducts
Inflammatory thickening of wall (Chronic cholecystitis)
Calculus overlooked at neck of Gall bladder
Calculus overlooked in cystic duct
Frequent location of stricture in supraduodenal portion of common duct
Duodenum
Common duct compressed by chronic Pancreatitis
Overlooked common duct Calculi above Ampula

Fig. 2.—Diagrammatic representation of the more frequent causes of recurrence after operations on the biliary tract.

The presence of many small calculi in the gallbladder, associated as it has been so frequently in my own experience with calculi in the common duct, seems to me to be an indication for cholecystectomy with removal of the entire cystic duct, which we must add to our other indications for this operation.

In a previous communication,[14] the subject of overlooked common duct calculi was discussed. Further experience has strengthened the opinions expressed in that article.

During the past five years, in the course of a large number of operations on the biliary passages, I have explored the common and hepatic ducts in thirty-four cases in which palpation was negative. In eleven of these (32.3 per cent.) calculi were found on exploration in spite of negative palpation.[20]

The chief indication for opening the common duct in eight cases in spite of negative palpation was the presence of many small calculi in the gallbladder. In all of the eight cases of positive exploration after negative palpation the number of calculi in the gallbladder varied from twenty to three hundred.

In three cases the common duct calculi were the size of a pea, faceted, and fifteen in number. In the majority of the eleven cases the calculi were found in the supra-ampullary portion of the common duct, which is so difficult to palpate through the duodenum. In two cases a number of small calculi of the same size and composition as those in the gallbladder and common duct were either found in the hepatic duct or escaped in a perfect shower from this duct while the edges of the opening in the common duct were retracted. In one of these patients there has been a recurrence of symptoms in spite of a cholecystectomy and choledochostomy with removal of calculi from the common duct. In one case symptoms of cholangeitis recurred three years later, and death was due to this cause.

The indications for opening the common duct were the same[21] as those first emphasized by Kehr[22] to which I have added the recurrence of symptoms of cholangeitis after previous operations on the gallbladder or common duct.

That common duct and hepatic calculi are so frequently overlooked is due to several causes. First, choledochostomy is considered to be a far more difficult operation and accompanied by a much higher mortality than it deserves to be, and this deters many competent surgeons from doing as thorough an operation as they ought to do. Second, we are accustomed to be content with palpation of the supraduodenal portion of the common duct, and unless this is positive or there are definite obstruction symptoms, one is apt to omit further operative interference. Third, recent articles[23] and my own experience reveal the fact that we must change our views in regard to the symptomatology of common duct calculi. There is a group of cases which I have termed the silent common duct calculi which show none of the symptoms hitherto thought characteristic of calculi in this location. In nine of my own cases in which no previous operations had been performed the principal symptoms were: 1. Pain, for months to years not to be distinguished from that due to the gallbladder. 2. Icterus, slight and only during attacks of pain in three cases. In two cases there had been distinct icterus during the attack. In the remaining four cases there was no icterus at any time. 3. Chills and fever, present in only two cases of the nine. 4. Variation of the common duct in size from a little finger to a thumb. 5. Hardness and enlargement of the pancreas in only three of the eleven cases.

---

[19] The same thing holds true for the common duct, and some of the cases of recurrence after drainage and removal of calculi are accompanied by the constant discharge of such crystalline débris from the T-tube. One can readily see how a recurrence of symptoms can occur if sufficient of this material collects in the common duct. A study of *276 common duct* cases by Bruning demonstrates that one can have symptoms of severe cholangeitis without the presence of calculi, and that these may persist after drainage of the common duct.

[20] I may be criticized for being unable *to palpate calculi in* the common duct; but when one considers that the greater portion of the duct must be palpated *through the entire* thickness of the duodenum and that the majority of the calculi were not larger than a pea and were embedded in thick bile, as a rule, I can readily see why they have escaped detection by others as well as myself *in the past*. Kehr (Arch. f. klin. Chir., 1912, **97**, 301), in 46 per cent. of thirty-six cases in which palpation of *the common* duct was negative, found calculi either in the hepatic ducts or the retroduodenal portion of the common duct.

[21] These indications are: (*a*) presence of many small calculi in the gallbladder or cystic duct; (*b*) chronic *pancreatis* (*c*X) thick walled, dilated common duct, and (*d*) when patients whose gallbladders have been previously removed are *reoperated on*, if the common duct is dilated or thick walled, and there have been symptoms of cholangeitis (icterus, chills, etc.).

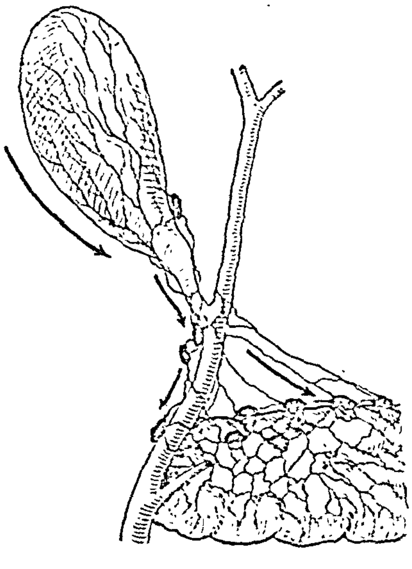

Fig. 3.—Relation of lymphatics of biliary tract to those of pancreas. Arrows indicate direction of flow of lymph from gallbladder and common duct to lymphatics of pancreas. Note relay lymph nodes at neck of gallbladder, along common duct and upper border of pancreas. (After Franke.)

As our knowledge of intrahepatic cholelithiasis increases, we are better able to understand why recurrences take place even after drainage of the common duct and removal of calculi. In one of my cases, calculi similar to those of the first operation were found at the second opening of the common duct, and this has been the experience of Deaver, Mixter and others.

When one has reason to suspect the presence of many calculi within the liver, prolonged drainage is our only method at the present time in order to lessen the chances of recurrence.

PANCREATITIS

Whether or not infection of the pancreas occurs as does that of the gallbladder in many instances by the hematogenous route is still under investigation. The close relation of the lymphatics (Fig. 3) of the biliary tract to those of the pancreas readily explains its involvement. The more chronic indurative forms of pancreatitis with resultant compression[24] of the common duct plays an important part in favoring stagnation of the secretory current in the bile ducts. In Deaver's series[12] of forty-two recurrences in 1,031 operations, chronic pancreatitis was the cause in five, a little over 10 per cent.

ADHESIONS, STRICTURES AND FISTULAS

"Adhesions" is often a diagnosis under which sins of omission are hidden, and should not be made until a thorough roentgenographic examination has been made. There are as a rule fewer adhesions after cholecystectomy, but even here one is often surprised to find a broad surface of the duodenum adherent to the carefully sutured gallbladder bed.

The longer a calculus lies impacted in the neck of the gallbladder or cystic, hepatic or common ducts, the greater is the danger of ulceration, with subsequent formation of a stricture. This is a strong argument for early and radical operation if the patient is not too septic. Fistula formation after operation is a rarity, since removal of the gallbladder is being employed as a routine measure by the majority of operators.

FAULTY TECHNIC

If only drainage of the gallbladder is performed, the method of anchoring the fundus to the parietal peritoneum should be discarded. It leaves a long tube fixed at both ends whose muscular contractions are greatly interfered with. Dropping the gallbladder back after insertion of a tube into its fundus is the most rational procedure.

The increasing frequency with which we find a dilated stump (Fig. 4) of the cystic duct, often containing one or more overlooked calculi, is the strongest plea for removal of the entire cystic duct close to the common duct,[25] during cholecystectomy.

INCORRECT DIAGNOSES AND COINCIDENCE OF TWO CONDITIONS

Coincident with the perfection of our methods of diagnosis, we find that many patients primarily operated on under the diagnosis of cholecystitis are in reality suffering from spinal lesions with referred pain, or tabetics whose visceral crises were interpreted as being genuine gallbladder attacks.

I have recently observed a patient with a gangrenous cholecystitis with many calculi who returned one year after a cholecystectomy with severe right upper quadrant pain which roentgenographic examination revealed to be a right ureteral calculus close to the kidney as the cause of the recurrence.

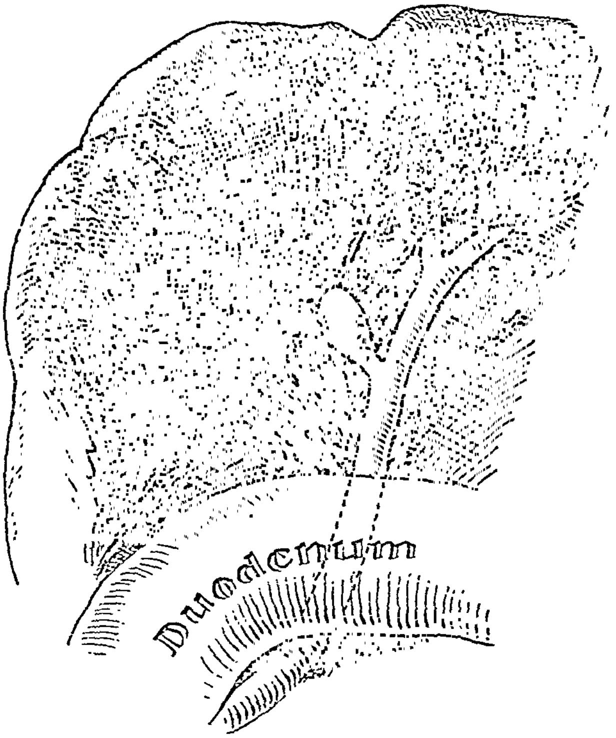

Fig. 4.—Condition found two years after cholecystectomy. Stump of cystic duct dilated to form new gallbladder. Latter contained small calculus.

TECHNIC OF CHOLEDOCHOSTOMY

I believe that drainage of the common duct has every advantage over primary suture as advocated by Crile.[26] He compares the common duct to a rubber tube with both ends patent, but he does not take into consideration the inflammatory swelling of the pancreas which invariably accompanies common duct infection and thus obstructs the exit of the infected bile through the ampulla.

---

[24] I have operated in cases resembling in every respect obstruction of the common duct by calculi, which were due to compression of the intrapancreatic portion of the duct by a chronically indurated pancreas.

[25] Under technic I refer to the anomalies of the mode of union of the cystic and hepatic ducts which must be borne in mind.

[26] Crile, G. W.: Drainage Versus Immediate Suture of the Common Duct, The Journal A. M. A., May 2, 1914, p. 1373.

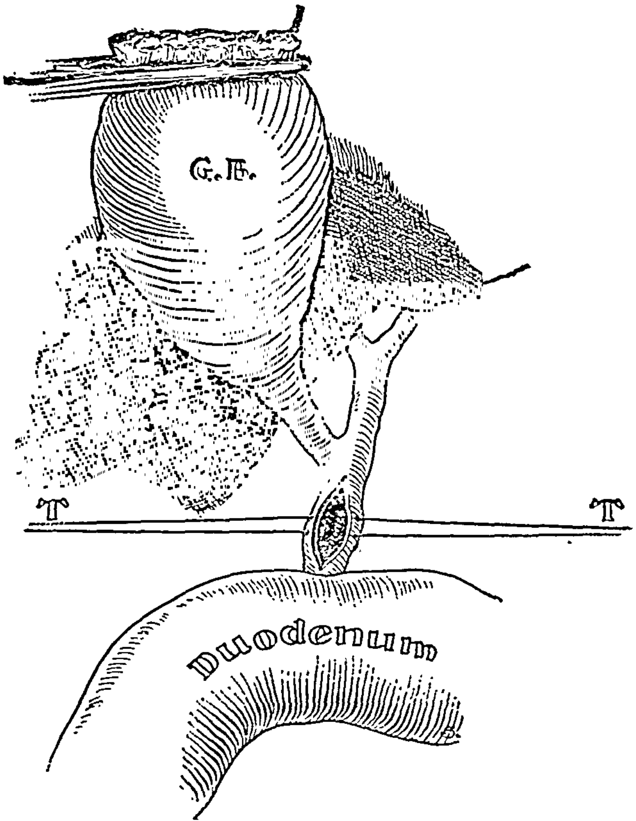

Fig. 5.—Supraduodenal choledochostomy. Edges of incision in common duct pulled apart by traction sutures (*T*, *T*) preliminary to exploration of common and hepatic ducts.

The steps of the technic which I employ are best understood by a study of Figures 5, 6 and 7.

Step 1.—The incision to expose the gallbladder extends from the angle formed by the ensiform process and costal arch downward through the inner third of the right rectus muscle to a little above the level of the umbilicus. The patient's lumbar region has been previously elevated by the device attached to the operating tables in common use. This incision not only permits the most perfect exposure of the common and hepatic ducts as well as the gallbladder, but also enables one directly to inspect the stomach and duodenum. It is surprising how close to the abdominal wall such an incision brings the principal bile passages.

Step 2.—After the stomach and duodenum have been inspected, the gallbladder is examined; and if calculi are contained therein, these are removed by the generally accepted method of an incision through the fundus of the gallbladder after its contents have been aspirated with the trocar and rubber tube attached to a 3-ounce metal syringe.

Step 3.—To expose the bile ducts, the fundus of the empty gallbladder is grasped by a long-bladed artery forceps and an assistant is instructed to make gentle traction in the direction of the right shoulder. This procedure also pulls the right lobe of the liver in the same direction, as first suggested by Mayo-Robson. The neck of the gallbladder, and the cystic, hepatic and common ducts are now exposed. If these structures are enveloped in adhesions, the exposure obtained enables one to separate and ligate the adhesions and to cover with suture raw surfaces by sight and not by touch. A very important detail in securing a good view of the common duct is to have the proper retraction not only of the gallbladder and right lobe of the liver, but also of the stomach, transverse colon and of the omentum, toward the left and in a downward direction. Such retraction is best secured (*a*) by the use of the Deaver and Kelly retractors, (*b*) by not packing too much gauze into the abdomen, and (*c*) by instructing the assistants (preferably only two being employed) only to keep up firm retraction and not to relax their grasp from time to time, thus permitting the viscera mentioned to drop into the field and cover the common duct.

Step 4.—In the surgery of the common and the hepatic ducts I prefer to employ instruments and suture material as fine as those used for eye operations in opening the common duct. The hepatoduodenal ligament is first identified as marking the right border of the envelope of peritoneum covering the common duct, portal vein and hepatic artery. Retraction of the structures (especially the duodenum) around the common duct permits the latter to be readily seen, covered by a thin layer of peritoneum which is divided by fine scissors, and the opening thus made is widened by spreading it with blunt-bladed curved scissors. Two traction sutures of very fine (00) catgut are inserted (Fig. 5) with an extremely small needle (such as is used for eye work) through the wall of the common duct in its supraduodenal portion. There are a few small veins which run parallel to the duct, and occasionally an anomalous small artery which passes transversely across the front of the duct. Bleeding from both of these vessels is easily controlled by a transfixion ligature. The duct is now incised with fine, preferably angular, scissors for a distance of one-fourth to one-half inch. It is a wise precaution before opening the common duct to place a gauze sponge into Morison's pouch over the right kidney. The opened common duct is now examined with a common duct spoon in an upward direction into the hepatic ducts and then downward as far as the ampulla until one feels certain that no calculi have been overlooked. A flexible probe is finally passed through the papilla in order to be sure that the lower end of the common duct is not obstructed.

Step 5.—In drainage of the common duct I prefer the T-shaped rubber tube first used by Kehr, which is now employed in this country by Deaver and others, including myself. The opening in the common duct is closed around this tube with the same size chromic catgut (Fig. 7) which was employed in the traction sutures described in Step 4. The tube itself (whose horizontal limbs should project only about one-fourth inch beyond the vertical portion) is held in place with a plain catgut suture.

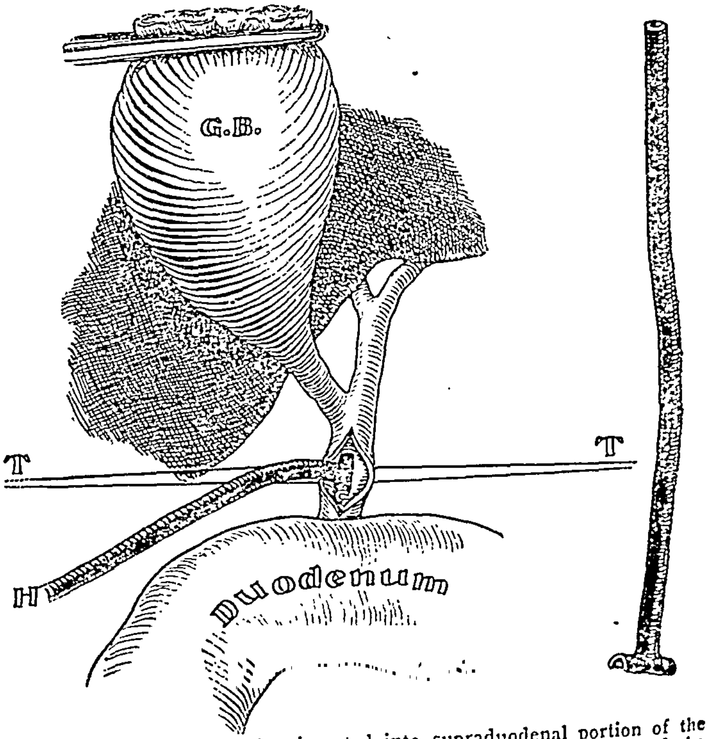

Fig. 6.—T-tube (*H*) being inserted into supraduodenal portion of the common duct through incision shown in Figure 5. The edges of the incision are pulled apart by traction sutures (*T*, *T*). Note on the right of picture how horizontal limbs of T-tube are only one-fourth inch long and how half of circumference of horizontal limb has been removed.

Step 6.—I prefer to do the cholecystectomy if one has decided that the pathologic changes in the gallbladder demand its removal, after the common duct exploration and drainage, because the gallbladder is a very convenient tractor for the common duct. Kehr reverses the steps by first removing the gallbladder and cystic duct close to the common duct, and then enlarging the cut end of the stump of the cystic duct so as to make an opening in the common duct large enough to explore both the latter and the hepatic duct, introducing his T-tube through the same opening.

The technic of cholecystectomy requires no special description. I first carefully separate the neck of the gallbladder and cystic duct from the common duct before ligating the cystic artery, which runs as a rule along the upper border of the cystic duct. The latter should be ligated as close (Fig. 8) as possible to the common duct in order to avoid the formation of a gallbladder in the dilated stump of the cystic duct. The careful separation just mentioned enables one to avoid injury of the common duct if, as frequently occurs, the diverticular-like enlargement at the neck of the gallbladder is adherent to the common duct, or if any of the anomalies in the course of the bile ducts described in another article[27] are present.

A small rubber tube is sutured with plain catgut down to the ligated stump of the cystic duct to take care of a possible leakage. Three strips of gauze 2 inches wide are placed around the common duct T-tube, one of these strips being placed well down into Morison's pouch over the right kidney. The gauze strips are pulled out at the end of eight days, and a single narrow one put in their place. The T-tube is allowed to remain from fourteen to twenty-one days,[28] and can be easily removed at that time; it will do no harm if it remains even longer. In nearly forty choledochostomies I have never encountered a case in which the tube could not be removed by employing gentle traction, and have never seen a common duct fistula follow its employment. I usually clamp the tube at the end of five or six days if too much bile is escaping into the dressing.

SECONDARY OPERATIONS BY THE AUTHOR FOR CASES OF RECURRENCE

1. *Persistence of Infection After Cholecystostomy.*—Case 1 (766).—Cholecystostomy for cholecystitis without calculi had been performed by another surgeon. There was recurrence of acute symptoms fourteen months later. A much thickened gallbladder was found anchored to the abdominal wall. Cholecystectomy was followed by complete cessation of symptoms.

Case 2 (1448).—Drainage and removal of a large calculus had been performed in 1910. There was persistence of pain, and then hyperacute symptoms of sepsis in 1916. Removal of thick walled gallbladder and drainage of common duct containing only tarry bile was of no avail. A toxic condition due to persistence of intrahepatic infection (cholangeitis) existed many years, with resultant hepatic insufficiency, and was the direct cause of death.

Case 3 (1431).—Cholecystostomy for cholecystitis without calculi had been performed by another surgeon in 1908. There were no symptoms until 1915, when a typical acute attack occurred. There was a very thick gallbladder with an area of gangrene at the neck, where a large calculus was impacted. Removal of the gallbladder was followed by absence of further symptoms.

Case 4 (314).—Two oval calculi, each 1 inch long, had been removed, and the gallbladder drained after suturing it to the abdominal wall, by another surgeon in 1896. There were no symptoms until 1908, when a sudden onset of severe pain occurred over the former incision. A secondary cholecystostomy was performed, with removal of two stones the size of marbles from a very rigid gallbladder. This is probably a true recurrence.

2. *Biliary Fistulas Due to Obstruction of Neck of Gallbladder.*—Case 5 (323).—There had been hydrops of the gallbladder with a large stone at the neck. Drainage and removal of the calculus had been done by another surgeon. Ulceration at the neck, where the stone had lodged, was noted at this first operation in June, 1915. A secondary cholecystectomy for persistent biliary fistula was performed. The fistula was due to a stricture at the neck of the gallbladder. Complete recovery followed.

Case 6 (618).—Cholecystostomy for cholelithiasis had been performed in 1906. A biliary fistula persisted until 1910. I performed a secondary cholecystectomy for very thick walled gallbladder with stone impacted in the cystic duct. There were no recurrence symptoms after the second operation.

3. *Persistence of Infection After Cholecystectomy and Drainage of Common Duct.*—Case 7 (895).—The first operation had been performed in 1912. This consisted of a cholecystectomy for a much thickened gallbladder containing many small calculi and showing acute supervening or chronic changes. The common and hepatic ducts were negative to palpation, but were opened because they were greatly dilated, and because of many small calculi being found in the gallbladder. Nine calculi ranging in size from a pinhead to a pea were found in the common duct, and a small number of similar ones were found in the hepatic duct. T-tube drainage of the common duct was done for four weeks. There was recurrence of symptoms one year later in the form of severe colicky pains and jaundice.

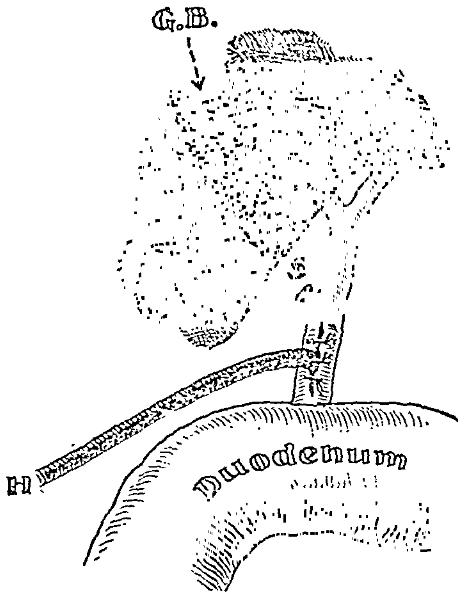

Fig. 7.—Appearance at completion of operation. Note liver bed from which gallbladder (*G. B.*) has been removed: also observe how close cystic duct (*S*) is ligated to common duct; and also T-tube (*H*) inserted into common duct.

The second operation was performed in 1915. Icterus and sepsis were the principal symptoms. The common duct was the size of two adult thumbs and was negative to palpation, but it contained a large amount of sandy detritus and small pigment calculi, as found in the previous condition. Septic symptoms were not relieved by drainage of the common duct, and the patient died a week later of septic pulmonary and enteric complications.

Case 8 (280).—There was a history of many years of recurrent attacks of pain and icterus. The first operation was performed in January, 1916. A thick walled gallbladder contained hundreds of small calculi and was removed. The common duct was negative to palpation, but fifteen calculi of the same size as those in the gallbladder were found lying in thick tarry bile just above the ampulla. There was no recurrence of symptoms for nine months, then severe pain and slight icterus appeared and have continued at intervals. Secondary operation was refused.

4. *Overlooked Common Duct Stones.*—Case 9 (657).—Cholecystectomy by another surgeon had been performed in 1910 for a small hard gallbladder containing two large calculi. Fragments of calculi and sandy detritus were found in the cystic duct. There was recurrence of pain and icterus

---

[27] Surgical Clinics of Chicago, August, 1917. The cystic duct, instead of emptying into the hepatic duct at an acute angle, may (a) run parallel to it for a variable distance, (b) wind around it, or (c) may empty into its posterior wall.

[28] Deaver strongly advocates prolonged drainage. He has left the T-tube in one patient for over three years.

two years later. At a second operation in 1912 the cystic duct was found dilated, forming a pseudogallbladder 1 inch long containing a calculus the size of a millet seed. The common duct was much dilated and negative to palpation, but two bean-sized calculi were found. The pancreas was very hard and lobulated. There were no further symptoms.

Case 10 (1426).—Cholecystostomy and negative exploration for calculi in the gallbladder had been performed by another surgeon in 1913. There was recurrence of symptoms eighteen months later (pain and icterus). At a secondary operation a much thickened but empty gallbladder was removed. The common duct was negative to palpation, but a stone the size of a navy bean was found. The pancreas was soft. There was no further recurrence.

Case 11 (1454).—The first operation by another surgeon had been performed in June, 1916. This was a cholecystostomy with removal of a large number of small calculi. The second operation was in December, 1916, a cholecystectomy by the same surgeon for biliary fistula due to overlooked stone in the cystic duct. There was recurrence of symptoms four weeks later (fever, icterus, pain). At the third operation in January, 1917, all the bile ducts were found much thickened and dilated. One calculus the size of a bean was firmly impacted in the papilla of Vater, and there were two smaller ones proximal to it. There was no recurrence of symptoms.

5. *Recurrence Due to Common Duct Injury During Cholecystectomy.*—Case 12 (1219).—Cholecystectomy had been performed after the removal of two calculi the size of marbles from a gallbladder showing many abscesses in its wall. Accessory cystic artery crossing behind the hepatic duct was overlooked with resulting severe bleeding and some narrowing of the hepatic duct during ligation of the vessel. The operation was followed by severe chills, fever and icterus. At a second operation, four weeks later, several small abscesses were found in the liver. The patient recovered from all cholangeitis symptoms except icterus, which has persisted. In this case the septic condition of the gallbladder favored liver infection after the hepatic duct had been narrowed.

6. *Recurrence After Cholecystectomy Due to Extrabiliary Causes.*—Case 13 (1303).—Cholecystectomy had been performed for grangrenous cholecystitis with many calculi in the gallbladder. The patient returned ten months later with severe colicky pain in the right upper quadrant, which was found to be due to a calculus impacted in the upper portion of the right ureter.

30 North Michigan Avenue.

ABSTRACT OF DISCUSSION

Dr. W. Wayne Babcock, Philadelphia: I would emphasize the value of cooperation between surgeons. Much good would be accomplished by observance of a rule that every surgeon should report back to the original operator the results he finds when the patient comes for a secondary operation. We know some of the bad results when our patients return to us. We know perhaps more of results of other surgeons, because the tendency is for our patients to go to others and the patients of others to come to us. If, therefore, we might have a surgical clearing house, or some method by which we could compare results, it certainly would be of special value in a subject so important as this.

There is no pathologic condition in the abdomen which is permitted to continue as many years without treatment as gallbladder disease. In the first stage of gallbladder disease, that before the formation of stones, there is one operation to be performed — cholecystectomy. From a study of Dr. Eisendrath's cases and those of others it will be found that there are then practically no recurrences. The second stage, in which stones have formed in the gallbladder, likewise is to be treated, for the most part, by cholecystectomy. In the first stage our mortality should be under 1 per cent.; in the second stage, not over 3 to 5 per cent. in the best hands. In the third stage, that of terminal complications, conditions are different; patients are older; there has been an interval of from twenty to thirty years from the inception of the cholecystitis to the operating table and the mortality exceeds 15 per cent. In this stage cholecystostomy, cholecystectomy and, especially, anastomotic operations must be considered.

Dr. John B. Deaver, Philadelphia: Dr. Eisendrath has called attention to a valid cause for the reformation of stones after a cholecystostomy by the persistence or recrudescence of infection lodged in the minute glands of Luschka. All of the eleven recurrent cases (in about 200 gallstone operations) in my experience at the German Hospital, Philadelphia, during 1916 and up to the present took place after a primary cholecystostomy. Gallstones had reformed in the gallbladder in two of the cases, and in one case stone was found in the common duct; in another case, in addition to stone in the gallbladder, sandy bile was found in the hepatic duct, where it had caused occlusion of the lower part of that duct. This patient had undergone a cholecystostomy four years previously at another hospital and a choledochostomy had been performed by me two years prior to this meeting. The recurrence of symptoms in the other case was due either to adhesions or to dilatation of the common duct (one case).

Dr. Eisendrath referred to two cases in which incision of the common duct, with retraction of the edges of the wound in the duct, was followed by the escape of a shower of small stones from the common duct. I have seen this in numerous cases of cholangeitis, pancreatic lymphangitis and chronic pancreatitis the result of long-standing gallstone disease. The establishment of permanent drainage in these cases has proved of marked benefit.

Pancreatic or peripancreatic lymphangitis I believe to be an important factor in causing the reappearance of symptoms in these gallstone cases.

The anatomic relationship between the lymphatics of the gallbladder and those of the pancreas, as has been shown by injection of the former through the latter, and the chain of lymph glands to the number of five or six along the cystic and the common ducts, easily explain how an infected gallbladder can play havoc with the pancreas, one of the most important organs in the body, not only because of its digestive function, but also because of its influence on the functions of other glands with an internal secretion. It is therefore of the utmost importance for the medical man not to dilly-dally with cases presenting symptoms of biliary infections, but to send them early for operation. Pancreatitis is the cause assigned for recurrence of symptoms in fully 10 per cent. of the patients who have come to me for reoperation. This is explained by the close anatomic connection between the common duct and the head of the pancreas, the latter when enlarged obstructing the duct.

Dr. E. MacD. Stanton, Schenectady, N. Y.: During the past ten years in collecting data on the end-results following gallbladder disease I have found that the actual facts, so far as I have been able to ascertain them, do not bear out a number of the conceptions vigorously maintained by many surgeons prominent in this work. It has been asserted that so-called cholecystitis without stones is a forerunner of gallstone disease; and that gallstones themselves are the results of an infection of the biliary tract by micro-organisms.

The latter assumption is, I believe, based on insecure data. The patients uncured of cholecystitis following cholecystostomy do not develop stones in a proportion greater than would be expected from the increasing age of the patients. The incidence of gallstones bears little if any distinct relation to demonstrable preexiting infection, but, on the contrary, does bear a distinct relationship to certain broad factors of sex and metabolism which point strongly to the assumption that the cholesterin-lipoid metabolism hypothesis of Ashaff, so well stated recently by Rothschild, is approximately the correct explanation of gallstone formation.

The actual available data show conclusively that so-called cholecystitis without stones and gallstone disease are etiologically as well as pathologically distinct and separate conditions. The symptoms in both diseases are similar, but the factors governing the end-results are different and, until we learn to separate the two groups whenever we attempt to estimate end-results, we shall continue to have confusion in our ideas on the subject. Cholecystitis without stones is not cured by cholecystostomy, but I want to emphasize that the end-results following gallstone operations bear no definite relation to the amount of infection in the gallbladder present at the time of the operation. Infection does occur frequently as a complication of gallstones, and this infection may greatly increase the dangers and difficulties of the operation, but provided all stones are removed and there be no coincident duct strictures, the complicating infection of itself clears up promptly and has little demonstrable influence on the end-results.

SACRO-ILIAC JOINTS IN OBSTETRICS AND GYNECOLOGY *

JENNINGS C. LITZENBERG, B.S., M.D.
Fellow of the American College of Surgeons
MINNEAPOLIS

There has been so much discussion during the last decade about the sacro-iliac joints and kindred orthopedic conditions causing sacrolumbar backache, that it ought to have been sufficiently impressed on the profession that pain in this region might be due to a condition in the back itself; yet many women are unrelieved of their suffering during pregnancy, are submitting to endless local gynecologic treatments, and are undergoing useless pelvic operations because they have never had their backs examined.

Many of these women, who have been "going the rounds" of physicians' offices, have a sacro-iliac affection as their sole trouble, or as a result of their pregnancy or gynecologic condition. The fact that I have seen many of them overlooked is my only apology for again laying stress on such a common symptom as backache.

The anatomy of these joints is still a subject of contention; Goldthwaite and Osgood,[1] Meisenbach,[2] Albee and others agree that the sacro-iliac articulation is a "true joint, having all the common joint structures, and naturally subject to the same diseases and injuries as other joints" (Goldthwaite).

The opponents of this idea aver that the articulation is a synchondrosis, immovable except under pathologic conditions. However, all agree that there is physiologic mobility during pregnancy.

When one sees a gynecologic case with the same symptoms as he finds in the demonstrable relaxation of pregnancy, and yielding to the same treatment, he may be justified in considering them the same thing.

Movement of these joints during pregnancy is amply proved by the enlargement of the inlet in the Walcher[3] position and of the outlet by the exaggerated lithotomy position, neither of which increases could occur unless the sacro-iliac joints permitted movement of the sacrum on the ilia. This has been recognized for years.

Cantin,[4] in 1899, demonstrated mobility in 98 per cent. of 500 cases, in 15 per cent. of which there were symptoms.

Snelling,[5] in 1870, called attention to the significance of these relaxations, and said: "Relaxation of the pelvic articulations becomes apparent suddenly after parturition or gradually during pregnancy, permitting a degree of mobility which hinders locomotion and gives rise to most peculiar distressing and alarming sensations." His warning, given forty-seven years ago, has not been generally heeded.

The first case that called Goldthwaite's[1] attention to relaxation of the pelvic joints was due to pregnancy. Even the numerous articles and abundant discussion started in 1905 by the paper of Goldthwaite and Osgood have not been sufficient to make the profession realize that every woman with a backache should have her back examined.

The results of relaxation in pregnancy vary from simple backache or even less than a definite ache, only slight discomfort, to an inability to move without the most intense suffering.

Most women, except in the very severe cases, believe backache to be a necessary part of pregnancy and to be endured with womanly fortitude. I fear that too many physicians think the same thing.

I shall not attempt to report in detail a long series of cases, but will confine myself to giving the essential points in a few cases which illustrate some phases of the subject. The milder cases give only moderate discomfort, which, however, on account of the constant prolonged irritation during pregnancy, give rise to nervous symptoms and are a large factor in the neurasthenia of pregnancy. I have seen a properly fitted combination maternity corset, abdominal support and sacro-iliac belt change an irritable neurasthenic, bemoaning her pregnant state, into a happy, contented, prospective mother.

REPORT OF CASES

Case 1.—This illustrates the extreme disability of pregnancy. Mrs. G. was eight months' pregnant, and was unable to walk without assistance; her figure bent in an attempt to protect the painful joint. Examination revealed left sacro-iliac relaxation, which was immediately relieved by tightly strapping the pelvis. She walked out of the office unassisted, erect and smiling.

Case 2.—This illustrates how pregnancy may initiate sacro-iliac trouble and be aggravated by subsequent pregnancies, and finally how trauma may cause almost total disability. Mrs. B. had pain in the back during her first pregnancy, had been fairly comfortable after her delivery, but had to wear a belt to insure complete relief; the difficulty returned during her second pregnancy, and now in her third I had advised wearing the belt to avoid trouble. In an automobile accident she was rendered almost entirely incapable of movement on account of the sacro-iliac pain. By substituting adhesive straps for her belt she was made more comfortable, but was not free from pain. After delivery she began to improve, and in a few months could go without her belt.

Case 3.—This case illustrates how easily a traumatic injury to the sacro-iliac joints may occur during pregnancy. Mrs. McC. went to the telephone; a rug slipped from under her as she arose, and in her attempt to regain her balance she was suddenly seized with a sharp lancinating pain in the back and fell to the floor. She found that she was unable to move, and had to be assisted to bed. When I saw her a few hours later I found an extremely painful left sacro-iliac joint, which was greatly relieved by strapping. I sent a trained corsétière to fit her with a combination maternity corset and sacro-iliac belt. This corsétière, who is a sufferer from sacro-iliac relaxation, wears a belt constantly, which she put on the patient to test her needs. The belt gave her so much comfort that she refused to give it back, and continued to wear it till her own was made. She had gone through two previous pregnancies without any backache.

Case 4.—This case illustrates the trouble first appearing in the puerperium. Mrs. S. had gone through her pregnancy comfortably. In the night of the first day after her delivery

she was suddenly awakened by a sharp excruciating pain in the back when she attempted to turn over in bed. When I saw her in the morning she had a very tender right sacro-iliac joint. Her pelvis was tightly strapped, followed by immediate, complete and permanent relief.

Case 5.—This was another case in which my attention was first called to backache during the puerperium. A couple of days after the delivery of Mrs. D., the nurse reported that the patient could not sleep on account of backache, which on examination proved to be a tender right sacro-iliac joint, which was relieved by strapping. When explaining the condition to this patient, I remarked that many women had the same condition during pregnancy and often would not complain when they could just as well be relieved. She said, "That is my case; I have had this pain almost all the time I have been carrying my baby, but I thought it was a necessary part of my condition and I did not want to appear 'babyish'." I now question all of my patients about backache, and thus save much unnecessary suffering, for if one waits for complaints, he will discover only the bad cases.

Case 6.—This illustrates the neglected case with final relief. Mrs. M. had characteristic symptoms of sacro-iliac relaxation during pregnancy. She was strapped with adhesive plaster, which gave her instant relief, but the adhesive was badly applied, resulting in blisters which provoked her, and she refused further treatment by belt or corset. She went through an uncomfortable pregnancy and puerperium. She resented any suggestion of treatment addressed to the pelvis, and went to an osteopath; receiving no relief, however, she finally returned, thinking she might have recurrence of a uterine misplacement, for which she had been treated. Nothing abnormal was found in the pelvis, and I reiterated my former diagnosis and insisted that she go to an orthopedist, which she did and was completely relieved with a 1 inch inelastic belt about the pelvis.

Injuries to the pelvic joints during delivery occur but are not within the intended scope of this paper.

The increasing size of the abdomen during pregnancy, like the pendulous abdomen, throws the center of gravity forward, to overcome which the back muscles are put on a strain, and the lumbar curve is increased, thus throwing the upper part of the sacrum forward. This attempt to restore equilibrium, being necessarily continued over a number of months, often results in sacro-iliac or muscular strain.

Every pregnant woman is a potential sacro-iliac patient. This is proved by the known relaxation, the demonstrable mobility in 98 per cent. of cases (Cantin[4]), and the fact that injury occurs more easily during pregnancy than at any other time. Stooping, lifting a child, a misstep, turning over in bed, or even normal movements, as arising from a chair, may precipitate a painful or even disabling condition. In my series of over 500 cases, 10 per cent. suffered enough to complain; and since I have inquired more carefully, I find that more than 20 per cent. acknowledge backache. For these reasons I believe every pregnant woman should wear a proper abdominal, back and pelvic support.

GYNECOLOGY

Retroversion, tumors and inflammatory processes in the pelvis not only cause pain in the pelvis but are so frequently accompanied by backache that this symptom is too commonly looked on as a pathognomonic sign of pelvic disease. It is, however, true that pain in the back directly referable to the sacro-iliac joints is often cured by correction of the gynecologic condition by operation or otherwise; on the other hand, it may work in just the opposite way, and the pelvic symptoms may be entirely due to sacro-iliac inflammation or relaxation, as I have repeatedly shown, by a disappearance of all pelvic tenderness by immobilization of the sacro-iliac joints. One must endeavor, therefore, to determine which is the primary trouble and address the treatment to that, which is not always easy. And again their interdependence is so close that neither seems to be more cause than effect, a true sacro-iliac and a real pelvic pathologic condition coexisting and each making the other worse, acting as it were in a vicious circle, the relief of one benefiting the other, but a cure of the patient resulting only when both are separately attacked.

The point, however, which I wish to emphasize is not the one so commonly recognized that backache is a symptom of pelvic disease, but the converse, that the backache may be an entity in itself; and not only that, but it may by referred sensations even simulate pelvic disease.

As Moore[6] says:

> In these cases all the pelvic organs are tender, presumably due to some intrapelvic condition; they have ovaries and tubes removed, are curetted, tamponed and douched without relief, and gradually drift into a neurasthenic condition of semiinvalidism. All of these cases should be cured or improved by proper treatment.

When one understands the distribution of the sacral plexus and the close proximity of some of the branches, especially the lumbar cord, to the joint, it is not difficult to understand how sacro-iliac disturbances could result in tenderness and pain referred to the pelvic organs.

Case 7.—This case illustrates the type of patient that has pelvic symptoms with no pelvic disease whatever. Mrs. P. came to the office complaining of backache and indefinite pelvic discomfort. She had had the condition ever since the birth of her first baby. She had "doctored for female trouble" for years, and had had tampons and every other conceivable topical application. A pelvic examination revealed a normal condition. The sacro-iliac joint was very tender on palpation. When I told her I could find no female trouble at all she looked very skeptical, if not disgusted, which feeling, however, quickly disappeared after I had strapped her pelvis; for this was one of those spectacular cases in which the patient gets immediate relief. Here was a patient who had been maltreated for years, had spent large sums of money, and endured great suffering, all for the lack of knowledge by her many physicians that backache may be due to something else than pelvic disease, the lack of complete examination and the neglect of well established diagnostic and therapeutic measures. She left the office without pain, wore the straps for a few weeks, never had a return of the pain, and somewhat to my surprise did not need a permanent belt.

Case 8.—This case illustrates two phases of this subject: first, that her symptoms, which she thought pelvic, were in the sarco-iliac joint; and second, that the condition of the joint was due to a remote condition, that is, focal infection. Mrs. L. was the mother of one child, aged 7 years. Several months before consulting her brother, who was a physician, she had noticed backache and more or less pain and heaviness in the pelvis. I was asked to examine her to find out what was the matter in the pelvis. I found nothing abnormal except some tenderness. On account of the pain in the back I examined the sacro-iliac joints, one of which was found quite tender. I thought the whole trouble was in the sacro-iliac joints. The pelvis was strapped with great relief, which, however, was not complete. In further search for the cause, roentgenoscopy revealed the focal infection of the teeth. Rapid improvement followed removal of all the offending teeth.

Young[7] says:

> Impairment of the sacro-iliac joints frequently invites disaster by offering fruitful field for the invasion of infecting processes.

---

6. Moore, S. B.: Virginia Med. Semi-Month., March 10, 1911.
7. Young, J. K.: Am. Jour. Med. Sc., 1912, 144, 96.

It is a far cry from pelvis to mouth, but well illustrates where we may be led if we follow our cases through a complete study instead of jumping at conclusions because the patient refers her pains to certain organs.

Much of the backache occurring during menstruation is in the sacro-iliac joints, owing possibly to congestion or relaxation at this time. Sometimes the relaxation is "so marked as to seriously interfere with locomotion." Wearing a sacro-iliac belt during menstruation often gives great relief.

In a series of more than 500 cases, many other reports could be given to prove the one point on which I wish to place emphasis, that backache and even definite pelvic symptoms may be entirely due to lesions in the sacro-iliac joints, or kindred orthopedic conditions.

However, when one is laying stress on a particular condition, one must avoid giving the impression that one believes it to be the sole factor.

I hope I may not fall into the obsession of believing that the sacro-iliac joints are the only cause of backache, even in the sacral region. I ought not, for I have seen many cases with other orthopedic conditions as the cause of this particular symptom, for example, shortening of one leg, flatfoot, lesions in the lumbar sacral joint, spinal curvature, muscle strain due to faulty attitude, and rupture of aponeurotic and muscle fibers.

CASE 9.—This case will illustrate how we may fall into such an error. Mrs. F. had been in a runaway accident fifteen years before I saw her. This was followed by severe backache, which disappeared in a few weeks and did not return until three years before, when she was suddenly taken with a "stitch" in her back when she stooped over to pick up a bottle of water, and could not straighten up. This was diagnosed as sacro-iliac subluxation, and so treated with some relief. I was asked after she had undergone three years of unsuccessful treatment to see if there was anything in the pelvis to account for the condition; examination revealed nothing. As most uncured patients do, she went from physician to physician and from specialist to specialist. Finally a diagnosis of separation of muscular attachments near the sacro-iliac joints was made by a prominent orthopedist, who gave her the greatest relief she had experienced by building up the shoe on the affected side and readjusting her corsets.

It behooves the obstetrician and gynecologist to remember that not all lower backaches, even with pelvic symptoms, are due to pelvic disease; the surgeon should recollect that they do not necessarily mean visceroptosis, dilated large intestine, appendicitis or genito-urinary affections; and the general practitioner, that the neurasthenic may have a real basis for her nervous symptoms in her back itself.

As Dunlop[8] says, the symptoms may be so vague or referred to so many places as to suggest the neurasthenic. He reported one case in which there were pains referable to the pelvic organs, appendix and genito-urinary organs. Even intestinal stasis was considered, and yet the patient was cured of all these by proper immobilization of the pelvic joints.

There is not time in this paper to take up the points of diagnosis. In differential diagnosis and treatment we must work in close conjunction with the orthopedist.

The principles of treatment are simple, calling in the main only for immobilization of the joints by adhesive straps, sacro-iliac belts or special devices, the application of which is described in orthopedic works.

Every pregnant woman, I believe, is a potential sacro-iliac patient. Therefore, I urge that she should be fitted to a specially designed maternity corset, which is a combination of abdominal support, sacro-iliac belt and corset back. It is so constructed as to get well under the abdomen, and really support it; it is provided with straps which may be tightened about the pelvis without constricting the abdomen; it has also a sacral pad, a high steeled corset back which gives the accustomed support to the back, and the whole is designed to correct faulty attitude and take the strain off the back muscles and sacro-iliac joints.

In the simple backaches of pregnancy or gynecology, I first use adhesive straps or the 1 inch inelastic belt for diagnostic purposes and to be worn till the maternity apparatus is fitted and made.

These simple devices usually suffice, but the more extreme cases often tax the skill of even the best trained orthopedists, with whom we must work in the closest conjunction.

The general practitioner can successfully treat most of the cases with adhesive straps, or the 1 inch inelastic belt tightly buckled about the pelvis over the ordinary corset, or by the sacro-iliac belt.

SUMMARY

The sacro-iliac joints are certainly movable during pregnancy, and while usually fixed in the nonpregnant state, may be movable under certain conditions.

This normal relaxation makes these joints very vulnerable; they are often the cause of discomfort, pain, displacement and even disability. Every pregnant woman is a potential sacro-iliac patient and should have her pelvis supported and faulty attitude corrected by a properly adjusted maternity corset.

Gynecologic affections may cause pain in the sacro-iliac region, and sacro-iliac lesions alone may simulate pelvic pathologic conditions; therefore every woman with sacrolumbar backache should have her back examined to make sure whether a pelvic or back trouble is the cause of the symptoms, or whether the two are coequal factors. The treatment of neither can be wisely decided until the exact rôle the other may play has been determined.

ABSTRACT OF DISCUSSION

DR. EDWARD REYNOLDS, Boston: I am confident that the long continued controversy among the orthopedists as to the cause of sacro-iliac backache, to which the essayist refers, is due to the failure of both sides to appreciate that there are several predisposing causes which produce much the same symptomatology, and temporary relief is often obtained from the same mechanical treatment. I think these backaches may be due to (1) actual looseness of the sacro-iliac joints; (2) to inherent skeletal disproportion, causing faulty posture, and (3) to intra-abdominal lesions which cause similar faulty posture. All these lesions create the same secondary disturbance, and, consequently, the same symptoms, since the symptoms are always the result of the secondary lesion, an overstrain and usually a consequent exudate in the lower part of the erector spinae muscles. The case is further complicated by the fact that any two, or sometimes all three, of the same lesions may be present in the same case, but the controversy has become so heated that neither side is ready to admit that the other may be partly right. The cases which the orthopedists see usually belong to one of the two first classes, while those which the gynecologist sees almost always belong to one or both of the two latter classes. The diagnosis between the underlying lesions rests necessarily on physical examination, both gynecologic and orthopedic, and difficult cases often demand consultation, and perhaps conjoint treatment, between experts in the two lines. I am in the most hearty sympathy with the reader's position that backache should be investigated in every case from both points of view, and also that it is not a difficult thing for a gynecologist to learn the orthopedic examination and so fit himself for a differential diagnosis in most cases.

---

[8] Dunlop: Virginia Med. Semi-Month., May 12, 1911, p. 66.

Dr. Robert L. Dickinson, *Brooklyn*: I have had the good fortune to have in my office a colleague who has trained me to know the loose joint and the faulty attitude. Like the reader of the paper, I have long practiced strapping and belting the joints and have secured a large amount of comfort from a very slight procedure. Therefore, I think no more important point has been made than that of the necessity of the routine examination of the sacro-iliac joints. The procedure of Goldthwaite, by which the patient lies full weight on the back and the leg is thrown forward with no flexion of the knee, will develop it in most cases. The method of Truslow, with the patient erect and a stethoscope over the joint to detect the sound is also a method of value. Dr. Reynolds also has lent symmetry to the discussion by insisting that we study attitudes both during pregnancy and in the gynecologic patient. The truth lies in neither of these completely. We must correct false attitudes and may thus cure backache, otherwise incurable, with a properly adjusted corset; or a weak back may be strengthened by muscular development.

Dr. Isadore L. Hill, *New York*: I feel that Dr. Litzenberg is to be thanked and congratulated for taking up for study and discussion one of the minor ailments of pregnancy. If any branch of obstetrics at present is neglected it is the study of these minor inconveniences. Although the woman is safeguarded against oversight with reference to her pelvis, which results in the necessity of serious measures at the time of her labor, for the most part women are still accepting the general attitude that pregnancy is an uncomfortable condition of necessity, and I think obstetricians are apt to neglect the smaller matters which it is possible to relieve.

Dr. Jennings C. Litzenberg, *Minneapolis*: I used the expression sacro-iliac and allied orthopedic conditions. That was simply an expression for giving in a sentence what would take a book to cover, and which Dickinson, Reynolds, Lovett and others took several years to work out. Every woman with a backache should have her back examined. This is not done. My sole object in bringing up this question was to emphasize a neglected minor condition, and if you will look at your programs you will see that the last sentence in my paper is a plea for more attention to minor symptoms. It is not, however, from the patient's standpoint a minor symptom. Why do we always emphasize the big thing? The discussion has fully justified me in bringing before you this little question of lower backache. I did not take any time to go into the diagnosis or treatment. Two or three have asked me how I applied these straps. They must be so placed that they are below the anterior superior spines and above the trochanters and applied tightly. This will give the necessary support and relief. We must correct faulty attitudes caused by pendulous abdomens, both in the pregnant and nonpregnant, by the high back corset. If I shall have succeeded in having the backs examined of some of the thousands of women who have backache, I shall be satisfied.

Ophthalmia Neonatorum.—The proportion of pupils blind from ophthalmia neonatorum in thirty-one state schools for the blind in 1916-1917 was, among a total of 2,961 pupils, 742, or 25 per cent. During those years the number of new admissions were 558, 109 of whom, or 19.5 per cent., were blind from ophthalmia neonatorum. Among the pupils in classes for the blind in the public school systems of Chicago, Detroit, Jersey City, Milwaukee, New York City and Racine, Wis., a total of 375 blind, there were 54, or 14.4 per cent., blind from ophthalmia neonatorum. This information has been tabulated in detail by the National Committee for the Prevention of Blindness.

BREATH SOUNDS IN INCIPIENT TUBERCULOSIS *

H. A. BRAY, M.D.
RAY BROOK, N. Y.

Alteration of the respiratory murmur is usually regarded as the initial, or among the initial, physical signs of early tuberculosis. A diversity of opinion exists, however, concerning the incidence of the various respiratory alterations and their relative value in diagnosis. Some authorities agree that the granular type of inspiratory murmur is the initial manifestation of the incipient lesion; others emphasize the prolonged high-pitched expiration as indicating early involvement, while still others attribute only slight significance to either of these changes. This confusion may be ascribed in part to the difficulty in distinguishing true pathologic changes in breath sounds from those variations which occur normally.

The present work was undertaken to determine, if possible, the clinical importance of altered breath sounds in pulmonary tuberculosis with the hope that any knowledge thus obtained might facilitate an early diagnosis. To this end a study has been made of the frequency and character of the respiratory changes in 124 cases of incipient disease confined to one or both apexes, and of the comparative significance of such changes when considered both alone and in conjunction with other physical signs and diagnostic procedures.

Although previous studies include a description of the breath sounds over the entire chest, the observations here recorded are restricted to the apex of the lung (a term herein employed to include that part of the lung above the second intercostal space in front and the spine of the scapula behind). This plan was adopted, because early in the present investigation it was discovered that a detailed study of the breath sounds over the entire chest subjected the patient to an undesirable physical strain. Furthermore, the apexes of the lung are particularly adapted for a study of this kind, since in tuberculosis the initial physical changes occur in these areas in approximately 90 per cent. of all cases. Finally, by confining the study to patients presenting only apical involvement, other conditions, which in themselves might alter the character of the breath sounds at the apex, were excluded and a more accurate idea of the modifications of the vesicular murmur in incipient disease was made possible. Among the conditions thus excluded are tuberculous involvement in parts of the lung other than the apex, spinal curvatures, deformities of the thorax, obstruction of the upper air passages, tumors of the mediastinum, marked deviations of the trachea, etc.

In the present investigation the following method was adopted: The entire chest was first auscultated superficially for the purpose of determining the normal vesicular murmur peculiar to the individual, a requisite for the correct interpretation of pathologic variation in breath sounds. Following this an attempt was made to locate the site of the lesion at the apexes from a study of the respiratory murmur during quiet then during slightly exaggerated, and finally, forcible breathing, the patient breathing orally and noiselessly and maintaining as far as possible the normal ratio between inspiration and expiration. These findings were then compared with the results of a complete physical examination, including the use of the roentgen ray and the fluoroscope. By studying the breath sounds before the other physical signs were elicited, and without knowledge of the roentgen ray and fluoroscopic findings, the examiner was uninfluenced by facts that might tend to color his interpretation of alterations in the respiratory murmur. Previous work had suggested the advisability of this plan.

---

* From the New York State Hospital for Incipient Pulmonary Tuberculosis.

Certain observations in physical diagnosis made by me in the course of previous work have been applied to the present study because of their aid in determining more precisely the value of respiratory alterations in tuberculosis. The application of these principles in this study helps to explain the discrepancies that exist between the present findings and those of previous observers.

These observations are as follows:

1. The employment of diaphragmatic breathing is an effective measure in differentiating granular breathing from those extrapulmonary sounds which simulate this type of breathing.

2. The observation of the time interval and force of the respiratory act is essential for the accurate differentiation of physiologic alterations in the duration and intensity of the respiratory murmur from those of pathologic origin.

TABLE 1.—FORTY-SEVEN CASES OF INCIPIENT TUBERCULOSIS PRESENTING A LESION AT THE RIGHT APEX

Granular breathing	1
Weakened breathing	5
Increased vesicular	3
Cog-wheel	..
Prolonged expiration	20
Bronchovesicular	6
No change in respiratory murmur	12
Total	47
Breath sound changes at the normal left apex	8
Weakened breathing	2
Increased vesicular	4
Prolonged expiration	1
Bronchovesicular	1

3. The lungs glide beneath the ribs during respiration is important in correlating pathologic conditions any given area is considerably greater than that represented by the bell of the stethoscope. This observation is important in correlating pathologic conditions with alterations in the respiratory murmur.

The present study comprises 124 cases classified as incipient according to the classification adopted by the National Association for the Study and Prevention of Tuberculosis. Tubercle bacilli were demonstrated in the sputum of approximately 24 per cent. of the cases. A comparison of the breath sound changes in the sputum-positive and sputum-negative cases failed to reveal any distinct differences, and for this reason they have been grouped together in the accompanying tables.

In eighty-one instances the lesions were unilateral, occurring at the right apex in forty-seven, and at the left apex in thirty-four. In the remaining forty-three cases the lesions were bilateral, slightly more extensive at the right in twenty-six, and at the left in seventeen.

The results of the study of the breath sounds in the 124 cases with apical involvement are presented in the tables. In those cases exhibiting more than one alteration in the vesicular murmur over an apex, only the most marked alteration has been noted.

Of the forty-seven cases of early disease with a lesion at the right apex, thirty-five, or 74.4 per cent., presented respiratory alterations, while twelve, or 25.6 per cent., gave no evidence of respiratory change. In eight instances the character of the breath sounds at the left apex suggested a lesion in this area, although further physical examination, the roentgen ray and the fluoroscope did not confirm this suspicion. Among the thirty-five cases exhibiting respiratory alterations, the inspiratory murmur was most affected in nine instances, the expiratory in twenty, and in the remaining six instances, the inspiratory and the expiratory murmur were about equally affected. In other words, in disease at the right apex, the expiratory murmur is altered more frequently than the inspiratory.

TABLE 2.—THIRTY-FOUR CASES OF INCIPIENT TUBERCULOSIS PRESENTING A LESION AT THE LEFT APEX

Granular breathing	1
Weakened breathing	10
Increased vesicular	6
Cog-wheel	1
Prolonged expiration	4
Bronchovesicular	2
No change in respiratory murmur	10
Total	34
Breath sound changes at the normal right apex	9
Weakened breathing	2
Increased vesicular	1
Prolonged expiration	4
Bronchovesicular	2

Of thirty-four cases of early involvement at the left apex, the findings were positive in twenty-four instances, or 70 per cent., and negative in ten instances, or 30 per cent. Respiratory changes suggesting a lesion at the normal right apex were noted in nine instances. Among the twenty-four positive cases exhibiting respiratory alterations, the inspiratory murmur was affected in eighteen instances, the expiratory in four instances, and in the remaining two instances both were equally affected. The respiratory variations at the left apex in contrast to those at the right are predominantly inspiratory in character.

In the forty-three cases in which the disease was bilateral, changes in the breath sounds suggested the presence of a lesion at both apexes in nine, at the right apex alone in fourteen, at the left apex alone in eleven, and in the remaining nine no changes in the breath sound were noted.

An analysis of the respiratory variations in forty-three cases presenting bilateral apical disease shows, as in those with unilateral involvement, that at the right apex the expiratory, and at the left apex, the inspiratory murmur is most frequently altered. In approximately 50 per cent. of the cases in this group, no respiratory alterations were detected, a fact explained largely by the absence of a normal standard for purposes of comparison.

TABLE 3.—FORTY-THREE CASES OF INCIPIENT TUBERCULOSIS PRESENTING A BILATERAL APICAL LESION

	Right Apex	Left Apex
Granular breathing	1	0
Weakened breathing	3	5
Increased vesicular	2	8
Cog-wheel	1	1
Prolonged expiration	12	4
Bronchovesicular	4	2
No change in respiratory murmur	20	23
Total	43	43

The results of the present study do not agree in certain essentials with those of previous observers, notably in the large proportion of cases (approximately 40 per cent.) in which the findings resulted negatively, and also in the difference in the incidence of the various respiratory modifications as observed at the right and the left apex.

COMMENT

Granular Breathing.—Granular breathing, or one type of the *rauhes Atmen* (rough breathing) of the Germans, is regarded by most observers as one of the earliest respiratory alterations in tuberculosis (Grancher, Minor, Turban, Sahli, Otis, Pottenger and Fishberg). For the satisfactory demonstration of granular breathing at the apex, the muscles in this region must be in a state of relaxation, because their active contraction may at times produce sounds indistinguishable from granular breathing, and thus lead to confusion in diagnosis. This requisite is obtained by means of abdominal breathing. In this type of breathing, respiration is conducted solely by the piston-like excursions of the diaphragm, the thorax is fixed, and the muscles in the region of the apex are relaxed.

Abdominal breathing, therefore, represents an efficient method for the elimination of those extrapulmonary sounds which arise in the contracting muscles and which simulate granular breathing. On the other hand, if the granular type of respiratory murmur is heard during abdominal breathing, one is justified in concluding that the vesicular murmur has undergone a definite pathologic alteration.

The value of abdominal respiration in the detection of granular breathing is illustrated by the fact that in a series of cases previous to its employment, the incidence of this sign in early tuberculosis was about 18 per cent., while subsequent to its use only three cases in the present series, or 2.81 per cent., exhibited this sign.

Changes in the Duration and Intensity of the Respiratory Murmur.—Since physiologic variations in the duration and intensity of the vesicular murmur may be confused with those of pathologic origin, a knowledge of the factors responsible for such variations in health is essential for the correct interpretation of their occurence in disease. When the volume of air inspired in a given unit of time is maintained, the intensity of the murmur remains unaltered. Thus, if on successive respirations the air intake is 500, 1,000 and 1,500 c.c., and the time interval occupied by the respiratory act is one, two and three seconds, respectively, no change occurs in the intensity of the respiratory murmur, since the air intake in a given unit of time (500 c.c. in one second) is the same in each instance. The depth of the respiration, however, is altered, as is the duration of the respiratory murmur. The view expressed by certain observers, among others Sahli[1] and Barker,[2] that intensity varies with the depth of respiration, is therefore open to question. Variations in the intensity of the respiratory murmur are due to differences in the volume of air intake in a given unit of time. The greater the volume the more intense the murmur, and vice versa. In other words, the duration of the vesicular murmur, more especially the inspiratory phase, depends on the time interval occupied by the respiratory act, the intensity on the force of the respiratory act. Variations in the force of the respiratory act may also alter the character of the respiratory murmur in the region of the apexes, a fact that increases the difficulties of diagnosis.

Normal variations in the duration and intensity of the vesicular murmur may be determined by observing the movements of the chest and abdomen and noting the time interval and force of the respiratory act. The detection of such physiologic variations is essential for the correct interpretation of similar alterations occurring with pathologic conditions.

As the movements of the chest during respiration are greater in front than behind, the examiner will find it advantageous to select the front of the chest when making such observations. By the adoption of this procedure, variations in the duration and intensity of the respiratory murmur have been reduced approximately 20 per cent. as compared with those obtained during a previous study of this sign.

In the present study the vesicular murmur was either weak or intensified, with corresponding changes in its duration in sixteen of the ninety instances of disease at the right apex, and in thirty-two of the seventy-seven instances of disease at the left apex.

Prolonged Expiration.—Prolonged expiration, first advanced by Jackson of Boston in 1833 as a sign of tuberculosis, is generally regarded as one of the first alterations in the respiratory murmur to appear in early tuberculosis. In ninety instances of disease at the right apex, prolonged expiration was the most frequent sign, occurring in thirty-two instances, or approximtaely 35 per cent.; while in seventy-seven instances of disease at the left apex, this sign was present in only eight instances, or approximately 10 per cent. At the left apex the changes in the expiratory murmur, as compared with those at the right apex, were not marked.

Physiologic prolonged expiration is invariably more marked at the right apex, and in some instances may be entirely confined to this region. According to Bandelier and Roepke,[3] it occurs at the right apex in 33 per cent. of healthy adults. The relative frequency and more pronounced character of physiologic prolonged expiration at the right apex and the inability on my part to differentiate with accuracy such alterations in the respiratory murmur from those of pathologic origin explain, in part at least, the high incidence of this sign at the right apex.

Prolonged expiration more marked at the left than at the right apex, on the other hand, forms one of the most trustworthy physical signs associated with disease at the left apex. Infrequent in early disease, its incidence increases with the advance of the disease.

In thirty-one instances of moderately advanced disease in which expiration was more pronounced at the left than at the right apex, the left apex exhibited a definite lesion in thirty instances, while in only one case was no evidence of a lesion demonstrable.

Bronchovesicular Breathing. — Bronchovesicular breathing occurred in ten of the ninety instances of disease at the right apex, and in four of the seventy-seven instances of disease at the left apex. Bronchovesicular breathing and prolonged expiration, because of their close similarity to each other, are frequently confused. In their differentiation the personal equation is an important factor. This point should be borne in mind in studying the present statistics.

For the correct interpretation of breath sound change, a knowledge of the movements of the thorax and lungs during respiration is important. It is generally assumed that no change occurs in the position of the auscultated field during respiration. For instance, the pathologic basis for one type of bronchovesicular breathing is explained by Turban as due to superficial aerated lung tissue overlying an area of partial or complete consolidation. The air current first impinging on the consolidated tissue gives rise to the bronchial quality, and later the expansion of the superficial air-containing lung produces the vesicular quality.

---

[1] Sahli: Klinische Untersuchungsmethoden, Ed. 5, 1908, p. 296.

[2] Barker: Monographic Medicine, 2, 518.

[3] Bandelier and Roepke: Die Klinik der Tuberkulose, Ed. 3, 1914, p. 69.

This explanation of bronchovesicular breathing presupposes that the lung is more or less a fixed and immobile organ, a view in accord with current ideas. That the contrary is true, however, and that the lung exhibits considerable movement on respiration, may be illustrated by the following procedure: If the bell of the stethoscope is placed over the lower margin of the lung and the patient directed to take a deep inspiration, at the height of inspiration the lower margin of the lung is no longer beneath the bell of the stethoscope, but may be 2 inches or more below it, depending on the fulness of inspiration. In other words, the lung glides beneath the stethoscope during respiration, and the area of lung auscultated over a given point in the thorax is therefore considerably larger than that represented by the bell of the stethoscope. The area of lung auscultated varies also with the type of respiration. This is illustrated by observing the movement of an isolated shadow in the lung by the aid of the fluoroscope and noting the difference in the position of the shadow with relation to the neighboring rib during thoracic and abdominal breathing. Clinically this change in the lung movement is shown by the striking variation that may occur in the size of the râle area in certain cases on abdominal and thoracic breathing. With the fact in mind that the lung glides beneath the ribs, bronchovesicular breathing may be explained by the presence of contiguous areas of consolidated and air-containing lung, which alternately pass across the auscultated field during respiration.

Furthermore, in the interpretation of the respiratory modifications other than bronchovesicular, and in those studies conducted for the purpose of correlating the physical signs and the roentgen-ray findings with those discovered at necropsy, the relative movements of the chest wall and the lung require consideration.

A striking feature of the data presented is the relatively large number of negative findings. Of the ninety instances with involvement at the right apex, the examinations were positive in fifty-eight and negative in thirty-two, while at the left apex in seventy-seven instances, the findings were positive in forty-four and negative in thirty-three. Among the cases presenting respiratory alterations, in many instances the variations deviated so slightly from the normal that the sign could be termed indefinite and merely suggestive. Of the eighty-one instances of unilateral disease, alterations of the respiratory murmur over the healthy apex occurred in seventeen, or 21 per cent.

The selection of the apexes for the present study and the difficulty encountered in this region in differentiating physiologic from pathologic changes in the breath sounds may explain the reason for the comparatively large number of cases in which the study of the breath sounds alone failed to prove of diagnostic value.

Finally, the present study indicates that expiratory alterations predominate at the right apex, while at the left apex the inspiratory murmur is most frequently affected, an observation which, if verified, would afford a reasonable explanation why certain observers have emphasized expiratory and others inspiratory alterations in the respiratory murmur in early diagnosis.

CONCLUSIONS

1. Abdominal breathing is an effective method for the differentiation of granular breathing from those extrapulmonary sounds simulating this type of breathing.
2. The observation of the time interval and force of the respiratory act is essential in the differentiation of physiologic from pathologic alterations in the duration and intensity of the respiratory murmur.
3. The lung glides across the auscultated field during respiration.
4. Variations in the force of the respiratory act may alter the character of the respiratory murmur in the region of the apexes.
5. Expiratory alterations predominate at the right apex, inspiratory at the left apex.
6. Prolonged expiration, when more pronounced at the left than at the right apex, is a reliable sign of disease at the left apex.
7. Bronchovesicular breathing may be explained by contiguous areas of consolidated and aerated lung that alternately glide beneath the stethoscope during respiration.
8. The frequency with which alterations in the respiratory murmur occur over the healthy apex in unilateral disease deserves attention.
9. Physiologic respiratory modifications interpreted as pathologic represent the most frequent error in the physical examination in early tuberculosis.
10. A study of the breath sounds in early disease is often difficult and misleading, and for this reason should not be unduly emphasized in diagnosis.

CERTAIN FACTORS IN THE ETIOLOGY OF GALLSTONES

ON THE BASIS OF THEIR CHEMICAL COMPOSITION

JACOB ROSENBLOOM, PH.D., M.D.
PITTSBURGH

The fundamental work of Aschoff and Bacmeister[1] has shown that gallstones are to be classified, as regards their chemical composition, into the following groups:

1. Pure cholesterol stones.
2. Stratified cholesterol-calcium stones.
3. Cholesterol-pigment-calcium stones.
4. Composite stones, composed of cholesterol and a mantle of cholesterol and calcium.
5. Bilirubin-calcium stones, usually found in the bile passages of the liver.
6. The very rare calcium carbonate stones.

The studies of Rothschild[2] and of Henes[3] have drawn attention to the possible importance of states of hypercholesterolemia in relation to the formation of the chelesterol gallstones.

These studies, together with those of Aschoff,[4] and of Chauffard,[5] and others of the French school,[6] have produced a reaction against the former explanation of Naunyn[7] as to the pathogenesis of gallstones. Naunyn concluded that the cholesterol of the bile is *neither a product of general metabolism nor a specific secretion product of the liver*, and that the chief source of the cholesterol in gallstone formation was from the degenerated and desquamated epithelial cells of the gallbladder and bile tracts. Aschoff and the French observers, however, finding no abundance of cholesterol in the wall of the gallbladder, do not accept this origin.

They believe that in the formation of gallstones the first step is the formation of a pure cholesterol stone without an inflammatory cause, owing to an actual increased excretion of cholesterol by the liver, or an excess of cholesterol in the blood, or because of resorption of solvent substances from stagnating bile. These primary cholesterol stones then produce an inflammation and occlusion, leading to the formation of the common mixed stones.

Rovsing[8] has also shown that Naunyn's conclusions cannot be accepted. He asserts that recent research seems to have established that, just as the urine becomes abnormally concentrated during the course of a febrile disease, the bile is liable to become less fluid. In the inspissated bile, precipitation is liable to occur and the elements thus thrown down may agglomerate into concrements. Among the facts on which he bases this assertion are the results of Boysen's chemical study of the gallstones found in 200 cadavers with cholelithiasis. The young, freshly deposited gallstones, and likewise the nucleus of all other kinds of biliary concrements, he found consisted of bile pigment and calcium, "pigmentkalk," as he calls it. Other elements of the bile are precipitated on this nucleus or are drawn in by osmosis, especially cholesterol. The conditions during pregnancy and during a febrile disease are liable to favor this inspissation. The concrements resulting from it are all of about the same age, confirming the transient nature of the cause producing them and explaining why new ones do not develop after the crop has been removed. Boysen found invariably that the gallbladder was sound when the gallstones were of the small, primary bile-pigment calcium type.

A still more conclusive argument in favor of this assumption of the origin of gallstones is that systematic bacteriologic study of the gallbladders removed in 320 cases at Rovsing's clinic between 1899 and 1914 showed that the organ was entirely sterile in fully 54 per cent., without a trace of infectious processes. The proportion in aseptic cases showing the different types of gallstones ranged from 52.7 per cent. of fifty-five cases in which a single large stone was found, to 77 per cent. of twenty-seven cases presenting the small mulberry-shaped stones. These findings demolish entirely Naunyn's theory that gallstones are deposited in consequence of an infectious process. Other data cited also disprove this, especially the fact that the symptoms of cholecystitis always follow, never precede, the gallstone formation. When the pigment and calcium are precipitated from abnormally thick bile, the resulting concrements may or may not irritate the gallbladder and ducts enough to set up inflammation. Rovsing reviews all the theories proposed concerning the pathogenesis of gallstones and shows the fallacies of each, while he expatiates on the way in which all the phenomena connected with cholelithiasis are logically explained by precipitation as the result of thickening of the bile under some temporary condition inducing transient inspissation.

ANALYSIS OF GALLSTONES REMOVED BY OPERATION

Case No.	Weight of Stones, Gm.	Water Per Cent.	Calcium Oxid Per Cent.	Cholesterol Per Cent.	Nitrogen Per Cent.	Remarks

This paper contains the results of analysis of the stones removed by operation in fourteen cases of diagnosed cholelithiasis. A careful history as to previous infectious disease was taken. The cholesterol was estimated by the method of Windaus.[9] The calcium was estimated by McCrudden's[10] method after ashing and extracting the ash with hydrochloric acid.

It may be seen from the accompanying table that in every case with a previous history of an infection the gallstones were chemically composed of calcium salts, while in those cases without a previous history of infection the gallstones were composed of cholesterol.

Mignot[11] and also Rosenow[12] have shown the relation of infection to the formation of gallstones. Rosenow found an almost complete absence of bacteria in four pure cholesterol stones, which seems to bear out the data contained in this paper, showing that the cholesterol gallstones are possibly not due to a previous infection. Churchman[13] has reported a case of acute typhoid cholecystitis with large amounts of calcium soap in the gallbladder, which also seems to show that the calcium stones are more apt to be due to an infectious process.

THE REDUCTION OF GASTRIC ACIDITY

PRELIMINARY ACCOUNT OF METHODS

EDMUND JACOBSON, M.A., Ph.D., M.D.
CHICAGO

It is generally admitted that the hydrochloric acid of the stomach comes from the sodium chlorid of the blood and that the body gets its chlorids from food and common salt. To do away with hyperacidity or hypersecretion what means is more logical and direct than to shut off the food supply of chlorids? Clinicians often take a first step toward this when they tell their patients with ulcer to avoid the use of salt. About six months ago my attention was drawn to the question when a patient returning to the use of salt had a marked increase of acid.

Dogs have been given food deprived of salts, and in most cases the gastric juice has fallen off in strength or amount. The work of Cahn, Wohlgemuth, Pawlow, Dastre and Frouin is convincing in this connection, although Pugliesse writes to the contrary. Usually the animal did not thrive on the diet poor in salt. One writer (Forster) who had fed his animals on food of this sort announced that they died more quickly than if they had been utterly starved! These findings made a profound impression: the absence of salt was blamed for the speedy death. Although the chemist Bunge protested that the death was due not to lack of sodium chlorid but to certain other deficiencies of the diet, and although one of his associates, Luinin, actually added this salt to the same diet and found that the animals still could not live on it, the impression remained current that experiments had conclusively shown that a diet quite lacking in sodium chlorid brings early death.

It may be admitted that food without inorganic salts will not keep up life. In treating hyperacidity we do not demand an absence of all inorganic salts, or even of the element sodium; we demand the absence only of chlorin. When the salts containing chlorin are removed from food, other inorganic salts also are removed; but later these other salts may be returned to the food, and the difficulty thereby obviated. So far as I know, no one has attempted to prepare a diet, well balanced and unobjectionable save that it lacked the single element chlorin, to discover whether the organism could get along on this diet and whether it would reduce the gastric acidity. Perhaps we should still find that "a very far going deprivation of chlorin may lead to general disturbances—which vanish after subcutaneous or rectal injections of large quantities of physiological salt solution," as Strauss warns. This is worth testing again. Even if untoward symptoms should arise and prove that the removal of chlorids can be carried too far, it is conceivable that a limit might be found at which favorable clinical results are achieved but beyond which one should not go.

Any diet used for the purposes in question must not be lacking in those elements essential to life sometimes called "vitamins." Early workers apparently did not know this. Luinin, as has been stated, deprived food of mineral constituents and found that his animals could not live on it even after sodium chlorid had been added; and so he went farther, restored the other inorganic salts, but still found that the animals could not live on the diet, although they did not die so early. However, the animals got along on milk alone. This point puzzled Bunge. "It is a noteworthy fact," he says, "that although animals can live on milk alone, yet if the constituents of milk which according to the present teaching of physiology are necessary for the maintenance of the organism are mixed together, the animals rapidly die." Today we might reply to this riddle that the constituents of the milk used failed to include vitamins—elements present in whole milk and essential to life. From all of this we learn to use diets well balanced in protein, fat and carbohydrate, lacking not in vitamins or inorganic salts or sodium, but only in chlorin.

Obviously there is need of more tests on man. Vincent announced in 1904 that a number of his patients with hyperchlorhydria had obtained real benefit from a diet poor in salts, and he did experiments to prove the point. Laufer confirmed his results, and more recently Enriquez and Ambard have published observations and warmly recommend this treatment for hyperacidity under certain indications. On the other hand, Leo gets discouraging results, while the experience of H. Strauss makes him very pessimistic. The latter warns that even after a prolonged salt-free diet — when the urine no longer has more than a trace of chlorids — the tissues persist in holding on to a supply of chlorin, which they furnish to the gastric glands, so that secretion of acid continues.

Here is a real difficulty. But perhaps it has been exaggerated. New methods may make this clear. Aspirations made every half hour or so for a period of hours will tell us about the total amount and strength of secretion for this time; we can compare the results obtained in this way before and after the chlorin-free diet. The curve of secretion thus obtained might show a lessening of secretion caused by the diet which would not be revealed by the older method of testing with a single daily aspiration. Furthermore, we can take special steps to meet the difficulty. Linoissier early pointed out that the favorable results with dogs were aided by drawing off the juice, thus ridding the system of chlorin. In man the gastric juice is conserved and resorbed in the intestine, and the same dose of salt can be used again indefinitely for the secretion of gastric juice. We must seek to promote elimination of chlorids by giving plenty of potassium salts (Bunge), avoiding the use of sodium bicarbonate, which decreases elimination (Goldberg and Hertz), by frequent aspiration, and by giving plenty of water (Rulon and Hawk). But if excess of water increases the gastric secretion, as they suppose, it may prove better to restrict the use of fluids.

The method of attack, then, is to use a diet well balanced save for lack of chlorin. The foodstuffs should be either naturally poor in this element or freed of it by boiling. To season his food the patient is given a special inorganic salt mixture of about the same proportions as found in milk by Bosworth and Van Slyke, except that calcium lactate is substituted for calcium chlorid. As these salts are also acceptable to patients with nephritis who are on a salt-free diet as seasoning in place of common salt, the following formula is given:

	Gm.	
Dicalcium phosphate	5	8
Monomagnesium phosphate	3	4
Dipotassium phosphate	7	7
Potassium citrate	1	7
Sodium citrate	7	4
Calcium lactate	4	

Mix and pulverize.

Important articles are fresh meat, potatoes, oatmeal, carrots and cauliflower, cut fine and then boiled for hours with several changes of the water; stewed apples, prunes and apricots; very weak tea and coffee; butter freed from salt by washing fine particles thoroughly in running water; one egg and about 50 c.c. of milk or cream per day, but no more. Distilled water is used for drinking, but if need be, tap water may be used for cooking if the chlorin content is low, as in Chicago.

Choice among the foregoing articles of course will vary with the nature of the disorder, the complications and the stage of treatment. Solid food may be hashed or mashed before serving. In some cases it might be well to begin with a period of starvation, following with the special diet; and later during convalescence the amount of milk and cream might be increased.

A sample diet for a day might be as follows: (The amounts of each article readily can be arranged to meet the caloric requirements of the individual.)

Breakfast.—Oatmeal gruel with sugar and a little cream; apple sauce; very weak coffee with sugar and cream.

Dinner.—Fresh meat, boiled and hashed; potatoes, boiled and mashed; carrots likewise; special salt-free butter; orange juice diluted and sweetened.

Supper.—One egg, raw, boiled or poached; boiled rice; purée of prunes; very weak tea with sugar and cream.

It is apparent that for gastric ulcer additional treatment may be needed, such as rest in bed, aspiration, and the administration of bismuth and alkalies, including calcined magnesia; but potassium bicarbonate will take the place of the sodium salt if it is sought to increase the excretion of sodium chlorid.

For the test meal either the Ewald or, better, several hundred c.c. of sugar solution, weak tea, or plain water may be given. The acidities are determined by titration, and the chlorids in the juice and daily urine are estimated by the McLean and Van Slyke method.

This preliminary account of work which has been under way since about May 1 is published in the hope that these principles and methods may interest others. The so-called "salt-free" nephritic diets of hospitals as a rule cannot be adapted for treating hyperacidity under this principle. A sample of "salt-free" bread from one hospital was found to contain a relatively high percentage of sodium chlorid. According to results with dogs, it is anticipated that about ten days or more of dieting may be required before a reduction of gastric acidity may begin to appear.

30 North Michigan Avenue.

Comparison of Salvarsan and Japanese Salvarsan Substitutes.—In Japan various substitutes for salvarsan and neosalvarsan have been placed on the market under such names as arsaminol, sodium arsaminol, ehramisol, neoehramisol, tanvarsan, neotanvarsan and arsemin. These Japanese preparations were tested pharmacologically on rats and dogs, and also compared with control experiments, using Ehrlich's old salvarsan. Clinical tests were also made in syphilitic cases. The workers, K. Dohi, H. Nakano and T. Kambayashi (Japanese Medical Literature, 1917, **2**, Part 2, p. 9, through Chemical Abstracts, Nov. 10, 1917, p. 2934) state that: "The toxicity of all preparations was noticeably less than the German one, although the possibility is allowed that the latter may have changed somewhat with age. The Japanese preparations seemed to have fully as much value as the original and yet lacked much of the reaction that usually accompanies the injections of the latter."

INTESTINAL OBSTRUCTION, COMPLETE AND INCOMPLETE *

JOHN WILLIAM DRAPER, M.D.
Fellow of the American College of Surgeons
NEW YORK

A complete obstruction of the bowel near to the stomach usually causes death in man and in the lower animals in less than 100 hours. A similar obstruction in the aboral portion of the intestine may not cause death for a week. An incomplete obstruction at any point in the intestine causes symptoms that differ from the complete form only in degree. Problems connected with obstruction are among the most interesting and important in medicine. What is the toxic agent which, with tachycardia and convulsions, but without elevation of temperature, destroys life so speedily in duodenal obstruction, leaving no discoverable trace at necropsy? Is it a product of bacterial infection, or is it due to perversion of the great glandular system of the alimentary canal? Is it analagous to the death caused by the removal of the parathyroid or other glands? Does the mere blocking of the intestine in this, biochemically the most active portion of the canal, amount to an actual severance of an interglandular relationship that is not compensated for through the blood vessels or other channels, an ancient and potent interaction that is necessary to the maintenance of life and for the continuance of which an open intestine is necessary? Why is it that the nonprotein nitrogen and other components of the blood increase enormously after duodenal obstruction, while no such change is noted in ordinary bacterial infection? Is a proteose similar to that described and isolated by Whipple the cause of death, or is the toxic substance, like prosecretin, of so delicate, evanescent and unstable a character as to defy detection by test tube analysis? If so, is not this an example of the truth of Haldane's recent assertion that we are emerging physiologically from a materialistic to a vitalistic basis of research? What is constipation if not a protective symptom analogous to abdominal rigidity which seeks to give surgical rest when and where needed? What relationship, if any, can be shown to exist between the well known chronic symptoms of intestinal toxemia and the little known but much dreaded symptoms of duodenojejunal obstruction? Why do certain of these chronic toxemics improve when the diseased and often pigmented cecocolon is removed? Is it possible to find any efficient medical treatment until some of the foregoing questions are answered? If surgical, is a given case to undergo resection or some form of anastomosis? What is to be expected of the different forms of anastomoses that produce partial exclusion? May there be recognizable hereditary structural changes predisposing to the occurrence of such chronic subobstruction as one often sees clinically in the chronic intestinal invalid? If so, may one utilize some such type of classification as that of Bryant—herbivores, carnivores and neutrals to aid in the diagnosis and care of these cases?

These are some of the engrossing problems which confront the student of atypical conditions in the alimentary canal. Some of them are answerable. Many are still open to free discussion. Of the remainder we frankly know little or nothing. It is axiomatic, however, that no treatment, either medical or surgical, can be of real value unless it is based on a greater knowledge than we at present possess. Researches, therefore, into the physiologic pathology of the alimentary canal are evidently of the utmost importance.

---

* Read before the Section on Gastro-Enterology and Proctology at the Sixty-Eighth Annual Session of the American Medical Association, New York, June, 1917.

Turning to a brief consideration of these questions, I may state that in a paper published eleven years ago from the Laboratory of Experimental Surgery at Columbia,[1] I related a series of experiments made during the previous years as a result of which we had concluded that neither shock nor the absorption of food products nor bacterial infection had anything whatever to do with death in duodenal obstruction. I found that by placing a triangular ligature between the stomach and the small intestine just aboral to the point of total obstruction, this ligature would produce drainage in about seventy-two hours, and that there was a very constant line, which I referred to as the lethal line of the duodenum, oral to which obstructions were fatal under the conditions indicated, but harmless if made aboral to it. From this, and from the fact that necropsies, most carefully and repeatedly made, failed to demonstrate any lesion whatsoever save capillary dilatation of the terminal colon and occasionally of the stomach and liver, I "determined that death was due to some more subtle factor than those considered . . . that there might be a relation between this form of intoxication, if such it be, in dogs, and the so-called tetany of human beings; that the question seemed to have resolved itself now into a determination as to whether death is due to an intoxication resulting from a disturbance of the balance of the secretions which pour so plentifully into the intestine in this particular region; . . . whether secretion or other secretions from the duodenum itself had anything to do with the cause of death."

In a paper published one year later,[2] quoting Wilms, I noted that death from duodenal obstruction subvenes with extreme rapidity, and that up to that date all patients were believed to succumb to toxic absorption, resulting from the decomposition of intestinal and stomach contents. Starvation and lack of absorption of water, which in those early days had already been thought by some to be a factor and which have latterly been brought into great prominence, notably by the valuable researches of Hartwell and Hoguet, were looked on as "hardly to be considered when one reflects that absorption of water takes place almost entirely in the colon, and can therefore not be materially influenced by the position of the obstruction in the small gut." Observations that we have made show conclusively that putrefaction has nothing whatsoever to do with the cause of death in intestinal obstruction.

In 1914, in a paper[3] based on researches made in the Surgical Research Laboratories of the Mayo Clinic and New York University, I concluded with Schultz that the power of the liver to pair camphor and glycuronic acid is impaired after duodenal obstruction. This is presumably an evidence of impaired liver function. It is, however, not reflected in the histologic appearance either grossly or microscopically.

The decrease in the water-content of the tissues in duodenal obstruction is about the same as obtains after salivation by pilocarpin for four days or after fasting for seven. As this decrease produced no visible change in either case before euthanasia, it is reasonable to believe that it produces none in intestinal obstruction. The loss is 10 per cent. The duodenal obstruction (death) undoubtedly arises from an interference with cellular reactions of the intestinal epithelium. The resulting toxins undoubtedly are at least in part eliminated from the stomach and colon.

I reported also the increase of nonprotein nitrogen in duodenal obstruction, concluding that all recent studies "point to aberrant activity of the duodenal and probably pancreatic cells; that the old hypothesis that the toxin is of bacterial or food decomposition origin may be discarded; that dehydration is of no greater importance in this than in other toxemias; that there is an important ratio between the toxicity of the intestinal epithelium and its digestive power; that the intricate syndrome autotoxemia in man will be better understood when we know the cause of death in duodenally obstructed dogs."

Through the courtesy of Professor Gettler of the department of chemistry, New York University, I am now able to report further studies in the chemical picture of the blood in duodenal obstruction in dogs, and to contrast it with his well known studies along this line in human intestinal toxemias and in infections. Thus a great deal of evidence has accumulated in the past fifteen years pointing to the accuracy of my hypothesis that death in duodenojejunal obstruction is not due to any form of bacterial action whatsoever, or to toxins derived from the food, but to a disturbance of the hormone or enzyme producing activities of the intestinal epithelium and the consequent production of toxic bodies that cannot be isolated by ordinary chemical analysis—in other words, that death is caused by conditions analogous to those induced by removal of the parathyroids or other glands. If this is true, and if my failure to corroborate Whipple's efforts to prove that a proteose is the cause of death is not due to inaccuracies, then the evidence points more than ever to the gland perversion or inhibition theory already referred to.

CHEMICAL BLOOD PICTURE IN COMPLETE DUODENAL OBSTRUCTION *

	Before Operation Per Cent.	Hours After Operation			
		24 Per Cent.	48 Per Cent.	72 Per Cent.	96 Per Cent.

* Dog 209, Department of Chemistry, New York University, May, 1917. No infection; no elevation of temperature; average pulse, 150; tremors; death, one hundred and tenth hour.

TECHNICAL STUDIES IN DOGS

Investigations with a view of determining the best technic for developmental reconstruction (right side colonic resection) were conducted by resecting 10 cm. oral and 10 cm. aboral, using the ileocecal valve as the dividing line. Three forms of anastomosis were used, "end to end"; "end to side" and "side to side." The majority of the animals developed a semisolid or watery stool after operation. Stools became normal in seven days, on an average. From a technical standpoint, lateral anastomosis was the easiest to perform. Although it was the most difficult and showed the greatest mortality, end to end anastomosis gave the best postoperative results. Dilatation of the oral end of the intestine was noted both in lateral and in end to side anastomosis. The "end to side animal" vomited postoperatively for several days, and was the worst as regards vomiting. There was less vomiting after the end to end anastomosis. Roentgenoscopy was applied to all animals within two and a half to three hours after the bismuth meal given before and after operation.

[2] Draper, J. W.: Is Death in High Intestinal Obstruction Due to the Absorption of Bile? (Rockefeller Institute Fellowship Research), Ann. of Surg., October, 1907.

[3] Draper, J. W.: Studies in Intestinal Obstruction, The Journal A. M. A., Sept. 26, 1914, p. 1079.

Roentgenoscopic interpretations:

Best results—end to end—no effect as regards delay, local or reflex.

Moderate results—end to side—moderate delay in stomach; no anastomotic delay.

Worst results—lateral—marked delay in stomach (reflex), slight at anastomosis.

Prof. George Wallace of New York University kindly directed for me the intravenous introduction of a chemical residue derived from the treatment (Whipple's technic) of 1,000 c.c. of proximal loop fluid from duodenally obstructed dogs by Professor Gettler, department of chemistry. We were unable either to cause the dog's death by intravenous injection of the entire amount collected, or to show any reaction whatsoever. Dr. Stark made the obstructions and collected the fluid.

SUMMARY

Our experiments on animals have led us to believe that death in high intestinal obstruction is due to a perversion of enzymal function. The symptoms are so fulminating in character as compared with those of obstructions aboral to the point of maximum physiologic enteric activity that until recently they have received far more attention both experimentally and clinically than those of the caudad obstructions.

This is true of both complete and incomplete types. It is the purpose of this paper to correlate the two and to show not only the close relationship which actually exists but also to point out the great importance of experimental surgery to clinical progress.

It is natural, after all, to expect that in a segment of the intestine so highly specialized as the duodenum, perversion of function should rapidly reach a climax. Here the most complex functions of digestion are consummated with rhythmic precision. It is not surprising that so gross an insult as must attend obstruction must be followed by violent biochemical reactions. A marked acidity of the gastric contents causes the pancreatic juice to be poured out, and initiates peristalsis in the gallbladder. Very high acidity causes a marked flow of bile. On the other hand, the cecocolon bears such a close resemblance to the stomach both functionally and mechanically, and these characteristics are so gross as compared with those of the duodenojejunum that they necessarily do not react so actively to interference. Embryologically they have practically the same developmental history. Until recently the cecocolon has received only limited study as compared to the stomach. This, too, is natural, both because of the nearness of the stomach to the duodenum, gallbladder and pancreas, and because many of the lesions of the colon are at first referred to the stomach. Only a few years ago Moynihan in his classic work on duodenal ulcer gave what he considered a typical picture of duodenal ulcer symptomatology which was thought to be pathognomonic, but which we now know can be caused by a chronic appendix, an elbow adhesion, a gallbladder, a long sigmoid or other lesions. He later admitted that it is almost impossible in some cases to differentiate intra-abdominal lesions through a study of their subjective symptoms alone. It is necessary to have a clear understanding of comparative embryologic pathology in order to appreciate the conditions often encountered when the human abdomen is opened. One is surprised to hear frequent and bizarre efforts to explain by mechanics atypical variations in the sigmoid that have a patent embryologic origin. The sigmoid and the cecum are two of the most variable organs in the body, and the esoteric stomach symptoms that arise are due to the variations rather than vice versa.

The intestine is developed by buds. This permits of wide variations in type. The primitive intestine is a good deal like that of the fish, two loops lying side by side. Like other theories that are mechanical in basis, the mechanical rotation of the intestine is now set aside, and it is shown to be a well ordered and systematic process depending on accommodation to existing conditions and regulated by intra-abdominal pressure. In the embryo the liver is so large that very little room is left for the intestine, and all the bowel, except its beginning and end, develops for a period outside the abdomen.

Now, as the liver fails to keep pace with the growth of the abdomen, the pressure within is diminished and the intestine gradually recedes within, until finally the primitive cecum and transverse colon accept the place allotted to them and gradually recede to a resting place over the duodenum and in contact with the kidney—the so-called second position. Here it remains until after birth, when it usually migrates toward the iliac fossa. During the process of rotation and subsequent migration, many irregularities may arise, which account for much adult pathology. Notable among these we may mention frequent delamination of the peritoneum and failure of fusion. My colleague, Jerome Lynch, has given much thought to these conditions. We believe that adventitious membranes are not in themselves harmful, but if, as a result of failure of fusion, partial obstructions periodically supervene, resulting in atrophy and pigmentation, as observed by our colleague, McFarland, in fresh cecal tissue, then those adventitious membranes are converted from normal peritoneum to connective tissue bands. Every one is aware that should this process continue, contracture follows and the typical elbow deformity previously described by us is inevitable. Furthermore, we are of the opinion that the dividing of normal extraneous peritoneal bands very often may precipitate what I have just described.

These physiologic and embryologic considerations help us to realize that, while there are great variations in the alimentary canal, it must be considered as a whole and that throughout it is subject to the same fundamental laws. What is true of one part is in a limited and discretional sense true of the rest, and this, in spite of the singular analogies between the gastric and colonic ends, which are purely mechanical, as contrasted with the duodenojejunum, which is almost wholly biochemical in action.

Thus, one is tempted to hazard the hypothesis that the syndrome in man called intestinal toxemia is really a subacute or chronic manifestation of the acute duodenal toxemia observed in obstructed dogs, modified perhaps in many ways by the toxins of a secondary bacterial infection. I have been forced to a favorable consideration of this hypothesis by an exhaustive study of twenty-nine cases of developmental reconstruction of the colon in which the right colon has been removed either by my colleague, Jerome M. Lynch, or myself, and recently reported by me.[4] Satterlee, Smythies, Einhorn and others have repeatedly noted that marked constipation can occur without the symptoms of toxemia, and it is evident that constipation is a protective symptom. We are miserable and stupid when constipated, but not because of the protective symptom constipation. We are constipated because of intra-enteric glandular disturbances similar to, but less severe than, those which occur in a duodenally obstructed dog.

That bacterial toxins serve to complicate the syndrome of autotoxemia is not to be questioned, particularly in view of the researches of Satterlee, who has achieved such marked results in otherwise hopeless cases through the injection of autogenous colonic vaccines. His recital of a fatal case of intestinal obstruction that produced such marked muscular spasm as to be mistaken for tetanus is a valuable addition to the literature. In Robert Brown's case of cecosigmoidostomy, which was afterward cured by the developmental reconstruction of the colon, the patient suffered from typical tetanoid seizures in the hands until relieved by operation.

Thus, our human and experimental animal studies continue to support the nonbacterial biochemical theory as to the cause of death in obstruction, and also to yield additional evidence that the symptoms of human autotoxemia have a common origin with those of a duodenally obstructed dog.

ABSTRACT OF DISCUSSION

Dr. Joseph C. Bloodgood, Baltimore: Dr. Draper was one of the first to call attention to duodenal death as a definite thing. I have seen duodenal death; I have had a case of it; at least, I thought it was duodenal death, and I performed an exploratory operation on the woman. I have seen postoperative duodenal death after a plastic operation for pyloric stenosis when obstruction was not there; and when the stomach had been resected and a gastro-enterostomy performed, it showed a kink and the duodenum closed in both ends. I have had two such cases in my own practice. I always think of it when I resect a stomach, and always try, if I must resect a stomach, to reestablish the continuity by suturing the duodenum to the stomach. There must be some experimental work along this line, and any man who devotes his time and labor to this work is one we should encourage in every way. I do not see much hope for the clinical side. I have the impression that it is one of the peculiar problems the progress of which must come from the experimental side.

Dr. Draper said he did not read the chemical part of his paper. This is really a discussion in embryology; but few medical students can discuss these matters intelligently. One of our greatest teachers has brought out the fact that in the medical curriculum we have exaggerated biology, while chemistry and physics are not given their proper place. There are few of us who can think in terms of chemistry, although we have had some chemistry. We have anatomic vision, pathologic and bacteriologic vision, but when it comes to chemistry in our profession, it is made conspicuous by its absence, except in a very few. One of the important things in changing the medical course today is the emphasis of chemistry and physics.

Dr. John Bryant, Boston: In 1910-1912 I had a very intimate experience with what medicine and surgery could do at that time for the chronic intestinal invalid. This experience was not wholly satisfactory; therefore, I concluded to make some personal investigations. As a result of my postmortem work I published a provisional classification of human types. This classification extended to man the use of the terms carnivorous and herbivorous as commonly understood in comparative anatomy.

There is a general impression, based doubtless in part on current textbooks of anatomy, that the human viscera are made on one model. This is not so. The intestine, for example, may be 10 or 40 feet long, but as in the lower animals, so in man, a short intestine tends to go with the long body form and a long intestine with the wide body form at a given height. All this affects the disposition and function of the viscera.

Dr. Lewis has reported from Worcester, on the basis of my classification, a series of 500 schoolchildren in whom only 10 per cent. were of a textbook normal build. In every ten of these children there was one normal to three of the wide or herbivorous type and six of the thin or carnivorous type. This was certainly a considerable variation on either side of the so-called normal, and was associated with definite variations in mentality.

Treatment of the chronic intestinal invalid must be approached simultaneously from three different points of view—mental, medical and orthopedic. Mental peculiarities must be considered, diet must be regulated, and with these must be employed reconstructive orthopedics.

In the practical matter of diet, I have found that though many invalids cannot take eggs, meat and fish for more than a few days consecutively without getting some sort of reaction, they may, on the other hand, often do well if the use of these three articles is restricted to two or three days in the week. They need the stimulus from these foods, but must get it through an alternating diet.

Dr. Jerome M. Lynch, New York: In listening to the discussion on constipation in this section I noticed that a great many men confounded constipation and autointoxication. Now, it does not follow by any means that because a patient is constipated that he is autointoxicated, or that because he has autointoxication he is constipated. It does not always follow that because a man or woman is not of normal type that that patient does not suffer from intoxication. I have noticed recently a great many women of the male type who suffer from a very marked type of autointoxication. In making experiments in ileocecal insufficiency I have become rather convinced that it is not really a surgical but a medical condition, for the sphincter can be closed by epinephrin. It is really remarkable how few men study a subject before applying a remedy. If the question of ileocecal insufficiency had been studied from the physiologic standpoint before it was studied from the medical and surgical or therapeutic standpoints, it would be seen that the problem was a question more of internal secretions than a mechanical one. Yet, I have heard one of our foremost roentgenologists say that it is entirely a mechanical problem. In 1822 a man named Goode drew attention to the fact that the ileocecal valve (so called) was not really a valve, but that it was a muscle, and one hundred years afterward, we have exactly the same problem presented to us showing that, notwithstanding the fact of the very wonderful studies of Elliott and other men, we have made very little advance.

The question of intestinal obstruction, both of the oral and aboral end, is interesting. The oral has received a good deal more careful scientific study than the aboral; the complete more than the incomplete. Dr. Bloodgood has done much pioneer work on the colon. I have done only thirty developmental reconstructions, as it has taken a long time to find out the type of case in which operation should be performed, and long, careful postoperative study extending over several years seems the best and only basis for decision. Draper and I are convinced that the symptoms of complete duodenal and incomplete colonic obstruction have a common origin in an interference with the internal secretions of the gut and its derivatives, the liver and pancreas, with secondary bacterial infection. These disturbances have been rightly called autointoxication, but it is a gross mistake to suppose that they are caused simply by absorption of decomposed food. This is supported by the studies of Boldireff on the periodic functions of the gut. The attendant constipation and diarrhea are probably protective rather than provocative. In the advances of the physiologic surgery of the gut we should never forget its debt to Mr. Lane, whose work, already superseded, gave the original impetus and placed us where we stand today.

---

[4] Before the 1917 meeting of the American Society of Gastro-Enterology.

Dr. John W. Draper, New York: I should like to add, in support of what Dr. Lynch has just said, that we have very interesting proof, I think, of the statement that constipation does not mean intoxication. We have usually performed a lateral anastomosis in removing the right side of the colon, and as just said, that results in a great deal of delay at the point of anastomosis. Nevertheless, in these cases the patients are often relieved of this intricate symptomatology which we call autotoxemia, although they are thoroughly constipated at the point of anastomosis, often for 100 hours, and it does not appear to interfere with their well-being. Constipation is a protective symptom and patients are constipated because they are autotoxemic, not vice versa.

TEN YEARS' EXPERIENCE WITH THE GRADING OF MILK

HENRY FIELD SMYTH, M.D., Dr.P.H.

Instructor in Hygiene and Bacteriology, Laboratory of Hygiene, University of Pennsylvania; Acting Secretary, Board of Health of Radnor Township, Delaware County, Pa.

WAYNE, PA.

In 1907, the board of health of Radnor Township, Delaware County, Pa., formulated a set of milk hygiene rules for producers of milk to be sold in the township, and as these rules have now been in force for ten years their effect on milk production and milk producers can be well seen.

Radnor Township is a distinctly rural community of the better class, consisting of the combined villages of Wayne and St. Davids, about 15 miles from Philadelphia on the main line of the Pennsylvania Railroad, having about 6,500 inhabitants and surrounded by a district of farms and country estates. It includes also a portion of Rosemont with several smaller settlements. The milk rules of the board of health govern not only milk produced in the township, but also all milk brought into the township for sale, the dairies producing such milk being subject to the board's inspection. No producer can register as a retailer or wholesaler of milk in the township unless he first files a certificate of health for his cattle signed by a competent veterinarian recognized by the board, and these certificates must be renewed every six months.

This paper does not attempt to give all the milk rules of the board, but gives only those referring directly to classification. These rules include a system of classification and grading of dairy farms which has so far given excellent results. The board from the first has recognized six classes or grades of milk. These grades are based on a combination of the use of the dairy score card, giving the results of a sanitary inspection of the dairy, the cows and the milk handlers, and of an examination into the methods employed, and the degree of cleanliness found; also on a frequent bacteriologic and chemical testing of samples collected at the farms and from the milk wagons at irregular intervals.

Class A milk must have a bacterial colony count of not over 10,000 per cubic centimeter, with no disease-producing organisms or peptonizers, and must come from tuberculin tested cattle with a dairy scoring of not less than 90 out of a possible 100 points on the score card, which entitles to the rating of an "excellent dairy."

Class B milk must have a bacterial colony count of not over 100,000 per cubic centimeter with no disease-producing organisms or peptonizers, and must come from healthy cattle with a dairy scoring of not less than 80, which is required for the rating of a "good dairy."

Class C milk must have a bacterial colony count of not over 500,000 per cubic centimeter with no disease-producing organisms, and must come from healthy cattle with a dairy scoring of not less than 70, which is rated as a "fair dairy."

Class D is pasteurized milk having a bacterial colony count of not over 1,000,000 per cubic centimeter before pasteurization and not over 50,000 per cubic centimeter after pasteurization with no disease-producing organisms.

Class E includes all raw milk with a bacterial colony county of over 500,000 from dairies with a score card under 70.

Certified milk from farms having the certificate of the Philadelphia Pediatric Society forms the sixth class, and is practically of the same grade as Class A milk.

The grading of dairies is done by the milk hygiene agent of the board, a trained veterinarian, and the bacteriologic and chemical examinations are made by the state livestock sanitary board laboratory and a commercial laboratory in Philadelphia, samples being collected and shipped by the milk hygiene agent or the health officer. Reports are made to the board quarterly, the classification in such reports being based on three or more surveys and milk examinations during the quarter. In case less than three surveys have been made, and this happens only with the new producers, the dairy is reported as unclassified. These quarterly reports are published as news by the local weekly paper, and many consumers are influenced thereby in the choice of a milk dealer.

The score card used in Radnor Township is the card recommended by the United States Department of Agriculture, with some modification to adapt it to local conditions. This card aims to place special emphasis on cleanliness and common sense in the handling of milk rather than on any special elaborate or expensive equipment or buildings. It has been found more than once that a careful, cleanly dairyman can produce excellent milk in an old fashioned country barn. On the other hand, there is abundant evidence that the best, most elaborate and expensive of dairy barns and equipment and the finest pedigreed stock will not insure a good rating without constant care and intelligent supervision. The grading of milk also includes consideration of milk temperature at dairies, in milk depots and on wagons, and an inspection of milk depots.

Table 1 gives a summary of the January reports for the ten years and shows very little change in the certified or pasteurized classes, but very interesting results in Classes A, B, C and E, illustrating the effect of continued inspection and publicity on milk producers as a whole. The sudden decrease in the number of producers in Class E seen in 1916 and their elimination in 1917 is due to the fact that in 1915 the board decided to prohibit the sale of Class E milk unless clearly labeled as "cooking milk," and after due notice this rule began to be enforced in April, 1916. As will be seen, this resulted in all of the Class E producers who would not or could not improve conditions going out of business. Of the eighteen producers in this class, in 1915, one half, or nine, when they found it necessary, succeeded in moving up into Class B or C, while the other nine simply stopped producing milk for sale.

Table 2 lists only Classes A, B, C and E, and gives the percentage of each in the total for each year and shows clearly a gradual and steady improvement from year to year. In the beginning there were over 59 per cent. of poor dairies, over 20 per cent. of fair, over 18 per cent. of good, and less than 3 per cent. of excellent dairies. A change was seen the first year in a lessening of Class E to under 42 per cent., with a corresponding increase of Class C to over 39 per cent. No very marked change is seen in the better classes until 1915, when, under the stimulus of the new rule, Class B increased from under 16 to over 40 per cent., while Class C dropped to under 18 per cent. In 1916, Class B lost one to Class A, but Class C increased from 17 to 40 per cent. at the expense of Class E, which dropped from over 38 to 18 per cent. In 1917, Class A gained two from Class B, and Class B increased from 36 to over 43 per cent, partly from Class C and partly from Class E. Class C showed a further increase from Class E, which was entirely eliminated. An added inducement for the higher class of producers was the fact that Class A milk has always brought about 2 cents a quart more than other milk, which the board feels is justified by its inspection and tests. For the first five years there was a steady lessening in the numbers of Class E, with a corresponding increase in Class C; but then through carelessness there was a change for the worse, and it was halted only by the introduction of the new rule requiring labeling of Class E milk.

TABLE 1.—CLASSIFICATION OF MILK IN RADNOR TOWNSHIP *

Class	January									
	1908	1909	1910	1911	1912	1913	1914	1915	1916	1917
Certified class, having certificate from Philadelphia Pediatric Society	2	2	2	2	2	2	3	3	3	3
Cass A, excellent dairy; sanitary score 90-100; bacterial colony count not over 10,000 per cubic centimeter; tuberculin tested cattle	1	1	0	2	2	2	2	2	3	5
Class B, good dairy; sanitary score 80 or over; bacterial colony count not over 100,000 per cubic centimeter	9	8	6	6	7	10	8	19	18	17
Class C, fair dairy; sanitary score 70 or over; bacterial colony count not over 500,000 per cubic centimeter	10	19	22	25	29	23	22	8	20	17
Class D, pasteurized; bacterial colony count not over 1,000,000 per cubic centimeter before and not over 50,000 after pasteurizing	1	1	1	1	1	1	2	1	2	1
Class E, poor dairy; sanitary score under 70; bacterial colony count over 500,000 per cubic centimeter	29	20	19	18	15	17	19	18	9	0
Not classified	....	....	....	....	....	3	1	2	4	
Total	52	51	50	54	56	58	57	53	59	43

* Based on the last three sanitary examinations of milk and the bacteriologic and biochemical tests of milk.

The decrease in the total number of dairies in 1917, as seen in Table 1, is due not entirely to the strict enforcement of rules, but also to the general economic situation. The high cost of materials, feed and labor has resulted, not only here but throughout the state generally, in discouraging many farmers from producing milk. This condition is probably less marked in Radnor Township than in many places, since, owing to the careful supervision of the milk supply, the consumers are more ready to pay a fair price for milk. When this work was begun, milk sold for from 5 to 8 cents a quart, while now few producers get less than 12 cents.

The results here shown were obtained not by the adoption of milk grading alone, but by constant intelligent supervision on the part of the milk hygiene agent. The aim of the board was not so much to do police work and punish delinquents as to do missionary work and encourage the dairymen to be constantly improving conditions. It has seldom been necessary to prosecute delinquents, and, after the first natural opposition to a new plan, the dairymen have come more and more to welcome the visits of the milk hygiene agent and to look to him for advice and help in planning improvements. In 1916, our agent received forty-seven requests for such advice and help. The majority of these were during the poliomyelitis epidemic. Also, consumers frequently ask him for advice in the selection of a dairy.

Strict impartiality is essential to success in dairy grading. Among the milk producers in Radnor Township are some wealthy gentlemen farmers with whom dairying is a hobby, and these receive the same treatment as the poorest farmer with only a few head of cattle. It occasionally happens that, on account of carelessness in the dairy, one of these farms is summarily removed from the excellent or good class to the fair or even poor class. On two occasions one of these dairies, not the same one each time, has been forbidden to sell milk at all until conditions were improved.

This brief paper will show what may be done in a rural community to improve the milk supply by the grading of milk producers, if accompanied by constant intelligent supervision and frequent examinations. Mild rules will not enforce themselves, however, and constant watchfulness is needed; but the Radnor board feels that time and money spent in this work is well worth while, and would regret very much to be obliged, for any reason, to discontinue this work.

TABLE 2.—PERCENTAGE OF MILK PRODUCED IN RADNOR TOWNSHIP IN CLASSES A, B, C AND E, BASED ON TOTAL OF THESE FOUR CLASSES *

Year	Producers in Four Classes	Percentage in Each Class				Total per Cent.
		Class A	Class B	Class C	Class E	
1908	49	2.0	18.4	20.4	59.2	100
1909	48	2.0	16.7	39.6	41.7	100
1910	47	0.0	12.8	46.8	40.4	100
1911	51	3.9	11.8	49.0	35.3	100
1912	53	3.8	13.2	54.7	28.3	100
1913	52	3.9	19.2	44.2	32.7	100
1914	51	3.9	15.7	43.1	37.3	100
1915	47	4.3	40.4	17.0	38.3	100
1916	50	6.0	36.0	40.0	18.0	100
1917	39	12.8	43.6	43.6	0.0	100

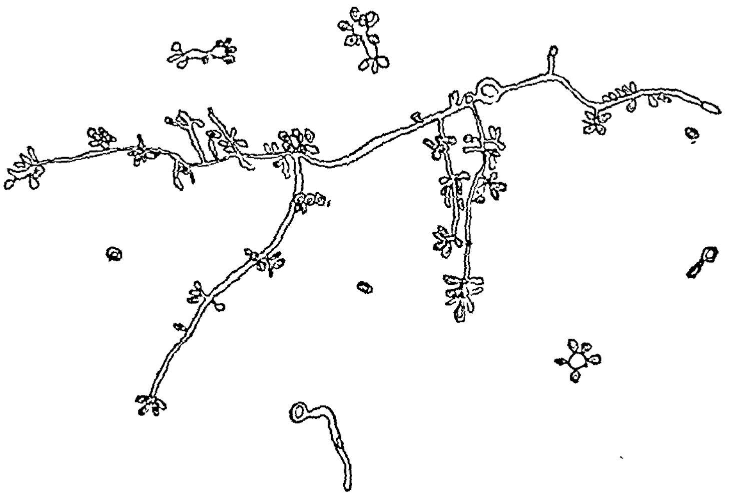
Insect Transmission of Disease.—Dr. L. O. Howard in a recent address before the Washington Academy of Sciences gave some statistics as to the number of insects which stand in etiologic relation to various diseases. Up to the present, discoveries have been recorded of the carriage of 226 different disease organisms to man and animals. An important recent discovery is that of the transportation by wind of the body louse, which is the carrier of typhus fever. In the *Bulletin* of the Pasteur Institute, Paris, for Dec. 15, 1916, there was a review of seventeen papers on the louse in connection with disease by authors of seven different nations.

AN ADDITIONAL CASE OF SPOROTRICHOSIS *

EDWARD H. McLEAN, M.D.
OMAHA

Although sporotrichosis has been known only since 1898 a considerable volume of literature has been published, and a constantly increasing number of cases is being reported. While the cases reported in America are still less than a hundred, this seeming rarity in its occurrence is due more probably to the fact that the condition is usually not recognized clinically. It often closely resembles syphilis, and the prevalent idea that a circumscribed, punched-out ulcer that refuses to heal should be strongly suspected as being caused by syphilic infection has led to the treatment of the condition with iodids, with resultant cures. The case is usually diagnosed as one of cutaneous syphilis, on account of the disappearance of the lesions under the iodid treatment. Though discovered first in America, the clinical bacteriologic aspects of this disease have been worked up most thoroughly in France, and there is a large amount of French literature on the subject. De Beurmann and Gougerot have contributed most largely to our knowledge of this condition. For a full description of the clinical and pathologic findings, with special reference to the various clinical types, the reader is referred to the article by De Beurmann.[1] The disease is most widespread in the organs it attacks, but so far only the cutaneous types have been described in the United States. Several species of the sporothrix are described in the literature, the most common being *Sporothrix beurmanni,* but an attempt to classify an organism which has been isolated, guided by the published descriptions, makes one agree with Meyer and Aird[2] in their conclusion that *Sporothrix schenckii* and *beurmanni* are of the same species, which is best called *Sporothrix schenckii-beurmanni.*



Four day culture on hanging-drop of 2 per cent. glucose agar. Outline drawing of actual microscopic field.

REPORT OF CASE

The case of sporotrichosis that is responsible for this note occurred in a patient from Winner, S. D. He was a Russian laborer, aged 33 years. He appeared at the dispensary of the Creighton Medical College for treatment. He gave the following history: About three weeks before appearing for treatment the patient noticed a small nodular swelling in the neck below the left ear. It was only slightly tender. Soon there appeared on the left side of the face from the bridge of the nose to the angle of the mouth, several similar swellings. These gradually became soft but caused only very slight pain. He complained of attacks of epistaxis and obstruction to nasal breathing. The patient stated that he had been caring for horses for the past few months, and that about four weeks before he became sick, the horses had been affected with a throat condition that he thought was glanders, though a clear history of the affection of the horses could not be obtained. The patient knows of no injury that he received that might have served as a point of entry for the sporothrix. The rest of the history is irrelevant.

Physical examination showed a patient apparently in good health. Below the left ear in the neck was a subcutaneous nodule about 1 cm. in diameter. There was moderate edema of the left eyelids. On the left side of the nose in the skin and involving the subcutaneous tissue was a swelling 3 cm. in diameter. It was soft in the center with an indurated periphery. Close to this on the side of the face were two similar nodules. They were about 2 cm. in diameter, hard at first but softening in the center in three or four days. After a few days similar nodules occurred at the angle of the mouth, and there appeared a submaxillary lymph node about 1 cm. in diameter. The nodules were purplish-red, elastic, with fluctuating centers and indurated edges, and were only slightly tender.

A clinical diagnosis of glanders was made and the patient was sent to the bacteriologic laboratory for cultures. The fluctuating lesion on the side of the nose was aspirated and about 1 c.c. of thick gelatinous pus obtained. Smears of this failed to show organisms. The pus was inoculated onto Loeffler's coagulated serum medium, blood agar, glycerin agar, and 2 per cent. glucose ovarian cyst broth. On the fourth day there appeared on the Loeffler's medium scattered small whites colonies which later became thickly wrinkled and leathery. In the broth there were tiny white cotton-like flakes lying on the bottom, with clear supernatant fluid. Smears from the solid mediums showed large numbers of oval spores with an occasional thread of mycelium. Some of the masses fished from the broth were tangled balls of mycelium which were divided by septa. In the meshes were numerous spores, some of which were attached to the sides of the mycelium by a fine stem. The organism stained deeply with the usual dyes and was Gram amphophile. The spores contained an eccentric and nonstaining refractile body. Subsequent transfers of the organism showed the best growth on 2 per cent. glucose agar. The growth in transplants appeared in forty-eight hours, at first as isolated white colonies, which later became thickened and leathery, and in from ten days to two weeks began to develop brown or black pigment. The growth tended to penetrate the surface of the medium, so that the medium was torn on removing any of the growth. In some cultures the growth remained finely granular, not developing the leathery appearance. In these the growth was confined to the surface of the medium. Attempts at anaerobic cultures were unsuccessful. The organism grew equally well at room or incubator temperature.

The development of pigment was variable. In some cultures none at all was formed. None was formed if air was excluded from the tube after the growth was obtained. In some tubes the color was uniform, being any shade from a light brown to a black, while in other tubes the surface was mottled. The advancing edge of the growth often was white while the center was deeply pigmented and this pigment was in the spores. Davis[3] has succeeded in obtaining pigmented and nonpigmented strains by securing his material for transplants from corresponding areas in the growth. These strains have remained true after many transplants and after animal passage. In the first two or three weeks the surface of the growth was shiny and moist, but after prolonged growth it was usualy covered by a fine powder due to spores on aerial branches. In cultures of several months' standing large oval bodies two or three times as large as the usual spores were found (chlamydospores?).

[3] Davis, D. J.: Chromogenesis in Cultures of Sporotricha, Jour. Infect. Dis., 1915, **17**, 174.

Cultures on hanging-drop agar showed the mycelium to branch irregularly, the spores springing from the sides by slender stems or grouped around the ends of the branches as pictured in the illustration.

This case adds another one from the Missouri Valley, where, according to Reudiger,[4] by far the largest number has been found.

Unfortunately the patient disappeared about the time the cultures were obtained and efforts to locate him were unsuccessful.

CANCER OF THE RECTUM AND THE PELVIC COLON

STATISTICAL AND CLINICAL REVIEW OF FOUR HUNDRED AND NINETY-ONE CASES *

JEROME M. LYNCH, M.D.
Assistant Surgeon, Medical Reserve Corps, U. S. Navy; Fellow of the American College of Surgeons
NEW YORK

I have seen to date 491 cases, which my associate, Dr. Giles, has tabulated (Table 1). Fifty-one patients died and 253 recovered, a mortality of 16 per cent. for radical excision. The remaining forty-one cases not included in the series were colostomies and palliative operative procedures for inoperable cases.

TABLE 1.—ANALYSIS OF FOUR HUNDRED AND NINETY-ONE CASES

	No.
Males	281
Females	210
Nature of Disease:	
Adenocarcinoma	451
Epithelioma	15
Colloid carcinoma	4
Scirrhous carcinoma	4
Round cell sarcoma	5
Melanosarcoma	5
Lymphosarcoma	4
Spindle cell sarcoma	3
Patients operated on	344
Radical excision	304
Simple abdominal section	20
Combined operation	111
Operations in one stage	75
Operations in two stages	36
Perineal	102
Kraske operations	20
Operations by modified bone flap method	32
Intrarectal operations	18

I feel very strongly that early colostomy in inoperable cases is as vital to the patient as early operation in operable cases. And I further feel that it is a great injustice to put off this operation until the patient is moribund. If colostomy is indicated, it certainly should be performed before the individual has become so weakened by the disease that the operation will be of no benefit.

There are so many inherited misconceptions with regard to cancer, and they are so firmly rooted in the minds of the laity, that it will require a long time to dislodge them. Reeducation is essential if we wish to progress. Textbooks on surgery, except the more recent, lay stress on age, pain, cachexia, loss of weight, and tumor as the cardinal symptoms of cancer. This is very misleading. Cancer knows no age; 0.5 per cent. of these cases are in children under 9 years of age; 2.5 per cent. of the patients are under 19, and in my personal experience 7 per cent. were under 30 and 9 per cent. were between 30 and 35 years of age.

The symptoms mentioned in the textbooks are those associated with the last or inoperable stage of cancer. Many of these patients seen by us had had unmistakable symptoms of the disease for over a year, although some of them had gained in weight.

The average duration of symptoms before admission is just over 8 months.

Total	491

Cachexia seldom appears until cancer is far advanced, and then principally in old persons and in those with cardiovascular diseases. One does not often associate pain with cancer of the rectum, except as a terminal symptom, and when the tumor is situated adjacent to the anus. In rectal malignancy the tumor can usually be felt with the finger, and on this examination alone a diagnosis can be made; but when the disease is situated in the sigmoid or the colon, the diagnosis is made in the former by means of the proctoscope. In the latter case, I admit that many difficulties are encountered in arriving at a conclusion. However, the roentgen ray and the natural inhibition usually associated with malignancy, together with the presence of blood in the stool and the reaction of occult blood, afford material aid in differentiating benignancy from malignancy. Except in advanced cases, an abdominal cancer can very seldom be felt, and then only in patients with a relaxed abdominal wall. Frequently, when a mass is found, it is an accumulation of fecal matter above the site of the growth, and not the tumor.

It is fortunate for the individual if this accumulation of fecal matter occurs early, as then, at operation, the malignancy is recognized. The late Dr. William Bull told me that he believed the day was not far distant when the public would be so educated as to accept exploratory laparotomy in every instance in which there is doubt. He lamented the difficulties he encountered in trying to convince patients that this was the proper course to pursue. If we could only remove from the minds of our patients preconceived notions of the immodesty of a rectal examination and insist on this in every case, many tumors would be discovered in their incipiency. Especially must we eliminate malignancy in cases in which there are constipation, diarrhea, hemorrhoids and loss of blood.

TABLE 3.—LENGTH OF TIME SYMPTOMS OF CANCER HAD BEEN APPARENT

	No. of Patients

When it is realized that 10 per cent. of my patients had had an operation for hemorrhoids within a few months of the time when I first saw them and that they might have been spared the suffering which followed those operations, we must feel convinced of the necessity of being thorough, and conclude that hemorrhoids are all too often the symptom of a worse malady.

---

[4] Reudiger, Gustav: Sporotrichosis in the United States, Jour. Infect. Dis., 1912, **11**, 193-206.

* Read before the Section on Gastro-Enterology and Proctology at the Sixty-Eighth Annual Session of the American Medical Association, New York, June, 1917.

Twenty per cent. of these patients had an incorrect diagnosis and were treated for stomach and enteric disease, when, in reality, they were suffering from a malignancy remote from these organs. It is well known that esoteric stomach symptoms are very misleading, but here again we are confronted by the lack of thoroughness.

We should make it a rule, no matter in what branch of medicine or surgery we specialize, to see that every patient referred to us has the thorough examination to which he is entitled. One fails to be thorough if one overlooks anything, and is guilty of neglect toward that patient.

Dr. John B. Murphy's advice to me, when I started to practice, was to examine every patient thoroughly, and if he refused such an examination, to decline to treat him. Nicholas Senn, on so many occasions, reiterated the necessity of a digital examination that I am sure most of his students followed his advice.

Many cases of carcinoma of the rectum are turned down as inoperable without due consideration. This decision is often influenced by the high mortality in the hands of some surgeons. Also, because in the past, a large tumor mass with the involvement of some unimportant structure was considered as a contraindication to a radical operation. I recall several instances in which this decision influenced the surgeon. But we should remember that cancer here remains stationary for a very long time, that the patient is facing certain death unless some effort is made to eradicate the growth, and that even if the patient should die in the attempt to save him, he is at least spared a great deal of horrible suffering. On many occasions I have found it necessary to remove the uterus, resect the vagina, remove a portion or the whole of the prostate, resect the seminal vesicles, resect the urethra, perform a radical Wertheim operation, resect several coils of the intestine and resect the bladder wall.

TABLE 4.—RESECTIONS IN CANCER PATIENTS

	No. of Cases
Removal of a part or the whole of the prostate	20
Resection of urethra, prostate and seminal vesicles	6
Resection of bladder wall	4
Resection of a part or the whole of the vagina	14
Hysterectomy complete	9
Wertheim hysterectomy	5
Removal of one or more coils of the intestine	6

One must expect a high mortality in such radical operations; but the percentage of cures is a sufficient justification to encourage us to continue and, if necessary, to do even more radical work. Dellman, in 1916, giving statistics for cancer in the Netherlands, says, in conclusion, that the more radical treatment of cancer nowadays is curing so many patients that the day is approaching, if not already here, when the number of deaths from malignant disease will no longer be an index of the actual prevalence of cancer. This is certainly encouraging, coming as it does from one who has evidently studied the subject very thoroughly.

The choice of operation in cancer of the rectum is always perplexing, and one that cannot be decided offhand; but it is safe to say that there are four operations, any one of which, when indicated, offers a solution to the problem.

Patients very often insist on knowing beforehand whether they will be left with a hole in their side, or whether it will be possible to restore the anus to its original site. Some men, in an effort to please, make contracts that they are unable to fulfil. This is unwise. In such a vital matter, the surgeon should insist that he be given full power to do what in his judgment is to the best interest of his patient. No surgeon should tie his hands beforehand and feel compelled, because of a previous understanding, to perform an incomplete operation when a slightly more radical procedure might prevent recurrence. I myself prefer to place the anus at its original site; but I never hesitate to leave a patient with a colostomy if by so doing I can get a better result. I never consider placing the anus high up in the sacrum, or in any other situation than the original site, because I believe that a colostomy is preferable to a stoma in any other than the normal position.

I agree with the surgeons who state that perfect continence can never be attained by attempts at restoration of the intestine to the normal anal site. Yet I have so many cases in which patients have enjoyed great comfort with this imperfect continence that I am convinced that this operation has a place in surgery.

Everything being relative, this applies with equal force to incontinence; and I feel confident that if a census could be taken of patients with relative continence, after a radical operation of the rectum, none of them would be willing to have a colostomy, in preference to a relative continence, with the anus in its normal situation.

My operation of choice is the combined operation, with the anus in its normal site in the perineum. This gives one the advantage of being able thoroughly to explore the abdomen. I know from experience that the under and diaphragmatic surfaces of the liver are first involved, and that only by abdominal exploration can this be determined. There are other advantages, namely, that one can perform a practically bloodless operation, and remove all the interglandular tissue and fat with a minimum of traumatism.

It is my custom, whenever possible, to block the sympathetic by the combined extradural and hypogastric anesthetization, as I feel that, by this method, shock, which is a bugbear to all surgeons in this operation, is obviated. I suggested to Dr. Halstead that this procedure accounted for my better results since I have followed it; but he seemed to think that it was due rather to a more perfect technic than to the combined blocking. Still, I nevertheless feel a good deal like the surgeons of the old school after they had washed their hands in mercuric chlorid, that it is at least a step in the right direction, adds no risk to the operation, and is in keeping with modern thought. The work of Crile confirms me in my belief, and so long as it does not add to the danger or the length of the operation, it seems well worth while.

The fact that a perineal operation was performed by me completely under sacral anesthesia must convince the most pessimistic of its value as a distinct method in blocking sensory impulses.

Whether the combined operation should be performed in one or two stages can only be decided at operation, and the surgeon is guided by his own experience and judgment. Often the anesthetist becomes alarmed during the course of the operation, but the surgeon familiar with this operation can always see the danger signal ahead. I prefer to perform the operation in one stage whenever feasible, but I am not inflexible in my judgment and never hesitate, if I feel that there is extra risk, to divide it into two stages.

The perineal operation is indicated in very fat persons and in those so debilitated that any form of abdominal exploration would be almost sure to result in death. In looking over my perineal operations, especially in that decade when this was the operation of choice, I find so many good results that it is hard to believe that this method should have such a limited field of usefulness.

Kocher many years ago pointed out that extensive glandular enlargement does not necessarily mean that those glands themselves are carcinomatous. I have had those glands examined at levels, and at various distances, from the growth, and in the majority of cases they have proved to be merely inflammatory. However, at the present date, it is much safer to explore the abdomen than to confine oneself to the perineal operation alone.

In all cases, no matter what the operation, I remove the coccyx as a matter of routine. It affords far greater room, obviates the pain that follows the operation when the coccyx is not removed, permits of thorough drainage, and adds materially to the comfort of the patient in subsequent dressings.

When the growth is situated near the anus, it seems advisable to perform a colostomy first. At the end of ten days, a wide incision is made of the tuberosities on both sides, and the growth is removed *en bloc* after the ischiorectal fossae are thoroughly cleaned out. I have succeeded in restoring the anus to its original site, and I have obtained a relative degree of continence for so extensive an operation.

I have found it to be of advantage to pack the pelvis by means of a device that has given great satisfaction from the standpoint of drainage, and has spared the patients unnecessary suffering during the removal of the gauze. No doubt this is nothing new, and has probably been used with equal satisfaction by others; but I mention it for the benefit of those who are unfamiliar with its advantages. A rubber glove, from which the upper halves of the fingers have been cut, and in which a small opening has been made in the palmar and dorsal surfaces to permit of drainage, is passed into the pelvis as tightly as necessary to control oozing and to fill up the dead spaces posterior to the bowel. At the end of forty-eight hours the gauze can be removed, the wound irrigated, if necessary, or desirable, and the glove repacked.

I have long since abandoned resection of the rectum, as early experience has taught that stricture inevitably followed. This is owing to the fact that the rectum has a terminal blood supply, and *not*, as is commonly supposed, to the lack of peritoneal covering. It is an axiom in pathology that *the amount of connective tissue is inversely proportionate to the blood supply.*

Kraske's operation has been abandoned by most surgeons, and I see very little indication for it in cancer of the rectum.

The sigmoid and cecum are two of the most variable organs of the body. The sigmoid, particularly, varies within wide limits, as in the case of Hirschsprung's disease. It possesses few lymphatics, has a dense fascial covering, and, for this reason, sigmoidal growths remain stationary for a long time. On account of its wide variation, it lends itself easily to resection.

There are many drawbacks to end-to-end anastomosis in this region, on account of the blood supply and the danger of leakage. Recognizing this, Mikulicz, Tuttle and others have suggested a three stage operation which has a low mortality, but like all safe procedures, has many inconveniences, in that the patient is incapacitated for a long time, and it may require more than one operation to close the stoma. It would also seem that the danger of metastasis would be enhanced by the subsequent handling and pressure, and by allowing the growth to remain in situ many days after the first operation.

For several years, except in cases of obstruction and in patients that are greatly debilitated, I have used the following technic: The sigmoid naturally rests in the iliac fossa, and this can be taken advantage of to make a lateral anastomosis between the two limbs of the sigmoid. The mesentery should be tied as in the Mikulicz operation. Both legs of the sigmoid are then brought together by a peritoneal suture on the inside. The intestine is mobilized toward the center, the pelvic and small intestines being carefully walled off. Following this, an anastomosis is made on the outer side of the parallel limbs. After the anastomosis has been completed, the sigmoid is allowed to fall toward the iliac fossa and is sutured to the parietal peritoneum, dorsad, cephalad and caudad. A small cigaret drain is placed above and below the anastomosis, and the abdominal wound is closed, except for the skin. Both limbs are double clamped, and the growth is removed with the cautery. After this the ends of the bowel are inverted, and the skin is closed in the usual manner. If leakage should occur it will be practically shut off by the two walls of the peritoneum. If there is any trouble with the anastomosis, the skin is opened up, and the cephalad portion of the bowel is opened and drained.

108 East Sixty-Fifth Street.

ABSTRACT OF DISCUSSION

Dr. George B. Evans, Dayton, Ohio: I have never seen a patient with carcinoma under 55 years of age. In cases in which the pelvis is much involved—by that I mean the vagina, uterus, ovaries and tubes, seminal vesicles, prostate and posterior urethra—I believe we should not extirpate or resect. Although we may give our patients temporary relief, their secondary sufferings are greater. I have never used the cautery because I feel it is better for me to have my finger up in the wound.

As Dr. Lynch has said, the question of diagnosis is by far the most important in these cases, and we should make it with the aid of the proctoscope, sigmoidoscope and roentgenogram. We should never operate in any case of carcinoma until we have given the patient's kidneys a thorough consideration. We should never operate on these patients until we have brought the phenolsulphonephthalein test to our aid. In the first ten years of my work, nearly all of my cases were operable, as I thought in those days. In the last ten years I do not think that in all the cases I have seen 10 per cent. were operable. I find that all the organs in these cases are *involved*. Therefore, and in conclusion I wish to emphasize that I believe we are going back to where we were, so far as the good of the patient is concerned—back to colotomy.

Dr. Frank C. Yeomans, New York: Every one in speaking of cancer of the rectum and cancer of the colon emphasizes early diagnosis, saying that if the surgeon gets the patient early *enough he will* cure him, no matter where the cancer is. Then they urge that we examine the patients carefully. I think all this is very good precept and practice; but many men who have been practicing for years never examine patients carefully. They do not take postgraduate medical courses, and they were not taught in the undergraduate schools the method of making a routine examination. The only way that we can hope to succeed in this, I believe, is to have courses of instruction in enteroproctology introduced into the undergraduate medical schools and make this a compulsory part of the curriculum, so that a student may become familiar with the average pathology of the bowel and know how to use the ordinary instruments of precision. Then, if he cannot interpret the findings, he will, at least, have the wisdom to confer with some one competent to make the diagnosis before the disease has progressed to a stage where it is beyond relief. Until that time the entire profession will not receive adequate instruction, cancer of the bowel will not be recognized early, nor will the patient receive the benefit of early operation.

Dr. William M. Beach, Pittsburgh: I should like to ask Dr. Lynch the tenure of life following these cases.

Dr. Dwight H. Murray, Syracuse, N. Y.: The microscope does not tell us the histologic factor. This may seem strange. I will explain by saying that in the examination of the cancer tissue removed, the pathologist will say that all of the growth has been removed and that the microscope does not show any cancerous tissue on the outside of the growth. In my opinion the microscope cannot show tissue which has been invaded and which has not yet shown pathologic changes that the microscope will reveal. I saw this thoroughly demonstrated in a case in which operation was performed a year ago.

Dr. John L. Jelks, Memphis, Tenn.: I am so pessimistic with regard to cancer of any part of the alimentary tract that I feel almost inclined to offer a resolution that it would be the sense of this assembly that late radical operations for cancer of the stomach and intestines are hardly warranted. I have operated and operated for cancers of the stomach, colon and rectum and the patients are all dead, or, if not already dead, going to die a little bit later of cancer of the liver. What is the use? I think it is best to turn the patients down. A number of men have said much could be done if we have "early cases." In the "early cases" the patients will not dream of having an operation and in the late cases we should not dream of operating.

Dr. Louis J. Hirschman, Detroit: I hope this paper will go out as a message from the enteroproctologist to the general surgeon and everybody doing surgery, to mark the passage of mutilating operations for the excision of a cancer; that the day of the sacral anus is over. I think the time has arrived when we must tell the profession at large that if they cannot do anything else than colostomize and implant the anus anywhere but at its normal site, they had better do nothing.

Dr. Jerome M. Lynch, New York: I am really sorry that my friend Dr. Jelks feels as he does; it is very unfortunate, for Dr. Jelks has many friends and a large following and the result will be that a great many patients with cancer who should be operated on will not be operated on. The statistics of Mayo and other men show that a great deal has been done in cancer.

Dr. Beach asked me for the tenure of life in these cases. Twenty-six per cent. of the patients are alive after three years (all these statistics will be published); two or three over sixteen years. When the average patient comes for operation he is over 50, and if he lives sixteen or seventeen years, he is going about the limit. So far as I can see, the results are very encouraging, and notwithstanding the pessimistic view taken by some surgeons, I shall still continue to perform these operations, and it will just mean holding the same position now that Samuel Sharpe held in 1820. Then he said, "Some men are so pessimistic about operation for cancer that they would rather let the patients die. In my own personal experience I have saved so many patients that I shall still continue to operate." It is almost 100 years since that time and we have the same obstructive pessimism to contend with.

MIXED INFECTION WITH THE PNEUMOCOCCUS IN EPIDEMIC MENINGITIS *

GEORGE MATHERS, M.D.
CHICAGO

In a recent communication, Netter and Salanier[1] report twenty-two instances of epidemic meningitis in which pneumococci as well as meningococci were found in the spinal fluid. These cases of mixed infection exhibited all the symptoms of meningococcic meningitis, but did not respond to serum treatment and terminated fatally. It is my purpose to call attention to the importance of these observations, and to report an example of this type of meningeal infection.

W. D., a boy, aged 7 months, entered the Cook County Hospital, Sept. 28, 1917, with all the physical signs of meningitis. According to the mother, the illness began suddenly two days before with convulsions, vomiting, stiffness and retraction of the neck, and a staring expression of the eyes. Otherwise the history was negative. The noteworthy physical findings were blindness, marked opisthotonos, orthotonus, and a positive Kernig's sign. The temperature was 103 F. and the pulse rapid and weak.

The spinal fluid was under increased pressure, opalescent, and contained 1,000 cells per cubic millimeter, 98 per cent. of which were of the polymorphonuclear type. Gram-positive and gram-negative intracellular and extracellular diplococci were present in the stained smears. The urine contained a trace of albumin and an occasional leukocyte, and the Wassermann test was negative. During the twenty days in the hospital, 185 c.c. of antimeningococcus serum were given intraspinally with no results. The temperature remained high and the child gradually became weaker and died, Oct. 18, 1917. A necropsy was not made.

During the course of the disease two bacteriologic examinations of the spinal fluid were made. In each instance a gram-negative and a gram-positive diplococcus were found in the cultures. The gram-negative organism had all the morphologic and cultural characteristics of the meningococcus, and was agglutinated by a polyvalent antimeningococcic serum in a dilution of 1:800. The gram-positive diplococcus was found to be a typical pneumococcus of Group I type. In the plate cultures of the spinal fluid in both instances, the meningococcus colonies were more numerous than the pneumococcus colonies. The spinal fluid had a faint greenish tint, and at no time was markedly purulent. Precipitin tests of the spinal fluid, in which the specific serums for both organisms were used, yielded negative results.

These observations emphasize the importance of frequent cultural examinations of the spinal fluid in all cases of epidemic meningitis, especially those in which antimeningococcus serum does not prove efficacious. Furthermore, they indicate that mixed infection may occur in meningococcic meningitis as in other infectious diseases, and exert an unfavorable influence on the clinical course. In the instance of mixed pneumococcus and meningococcus infection, combined serum treatment, as advocated by Netter, would be indicated. In regard to the general significance of this new observation in epidemic meningitis, it is sufficient to say that the importance of mixed infection in acute infectious diseases cannot be overestimated. The presence of two virulent organisms in the same pathologic lesion must not be neglected on the basis that one is a secondary invader; the activities of each organism must be reckoned with in the treatment.

Military Medicine and Surgery

SHELL-SHOCK *

A DIGEST OF THE ENGLISH LITERATURE

HENRY VIETS, M.D.
First Lieutenant, M. R. C., U. S. Army
BOSTON

In the last three years, the neurologists and psychiatrists of the United States have viewed with interest the reports that have come to us from abroad regarding the remarkable war neurosis, shell-shock. While these papers excited our interest, it was not until our country entered the war that the problem became one that demanded our serious attention. At the present time, however, we ought to be fully acquainted with the data already accumulated by foreign workers in the three years of war; to be able to give successful treatment in the many cases that are sure to arise in our armies and, vastly more important, to gain a clear insight into the condition so that we may be able to exclude from our draft army at the time of enlistment the men most liable to shell-shock, and thus prevent "the wastage of the recruiting office," which has been such a burden to the European countries.

Moreover, the importance of the problem cannot be overemphasized. Osler,[1] in a recent communication, speaking of the neurasthenic as he appears at the recruiting station, says that the unfit should be checked at the recruiting office and kept at home; "the trenches is no place for a man with unstable vasomotors. In the strain of war they break like dry twigs and become a heavy burden in the hospitals and convalescent homes."

June 1, 1917, Dr. Thomas W. Salmon, in a letter to the National Committee for Mental Hygiene, wrote from London in regard to the shell-shock cases:

> The extent of these casualties is almost beyond belief. I have not yet had access to the official records, but apparently the neuroses constitute one of the most formidable problems of modern war. These people are certain to go to pieces in the presence of danger or hardship, and are not only useless to themselves but are also a serious drag upon their comrades and the army in general.

When one sees, also, the vast number of these patients collected in England in the various special hospitals devoted to their treatment, one cannot but realize that, if we, in this country, could only prevent such wastage, our work would be of inestimable value to the government. Therefore, in view of the importance of this problem, one feels fully justified in bringing to notice the work already done on the subject by British neurologists and psychiatrists.

SHELL-SHOCK

The term "shell-shock" came into use in the English army the latter part of 1914, but the first reported cases that I have been able to find in the English literature were by Myers[2] in February, 1915. He reported three cases under the term "shell-shock" with loss of memory, vision, smell and taste. He expresses the opinion that his cases "appear to constitute a definite class among others arising from the effects of shell-shock." Even at this early date it was found that the term "shell-shock" was a very loose one, and that many of the patients coming back from France to England in this group had never been "shocked" by the concussion of a shell, but had been buried under débris when the shell exploded; in some cases the patients had never been under shell fire at all. March 27, 1915, the *Lancet*, in an editorial, commented on the effect of shell explosion on the central nervous system, especially in its relation to the special senses, and thought that most cases would fall into one of three classes: fatigue-paralysis, "commotio," or traumatic hysteria. In other words, the numerous cases with protean symptoms of nervous disorder were being thought of from the etiologic standpoint, and the neurasthenia and hysteria cases were being separated from those of supposed commotion or concussion with probable organic brain changes due to trauma.

It was not, however, until February, 1916, that we had the first clear classification of the shell-shock cases. Mott,[3] the London neuropathologist, in a series of lectures on "The Effects of High Explosives Upon the Central Nervous System," divided his cases into three groups from the pathologic point of view:

1. The immediately fatal.
2. The wounded with injuries to the central nervous system.
3. The traumas to the central nervous system without visible injury.

The last group, according to Mott, forms the true shell-shock cases. Thus, from the pathologist's point of view, all cases are "commotio" with or without visible injury to the central nervous system. Shell-shock, however, as seen from the practical clinical point of view, includes all functional or obscure neurologic cases. In many cases now grouped as shell-shock, the patients have never been within the zone of active warfare. Henry Head,[4] in a protest against the use of the term "shell-shock," is quoted as having said that it represented "a heterogeneous collection of different nervous affections, from concussion to sheer funk, which have merely this much in common, that nervous control has at last given way. To me it would be just as reasonable to sweep up the various fruits which fall from the trees in a strong wind and then to discuss them without first stating that some fell from an apple and some from a pear tree."

A workable classification from the clinical point of view is that of Buzzard[5]:

1. Pure exhaustion cases. These were quite common in the early part of the war, but are rarely seen now.
2. Neuropaths and psychopaths, who develop shell-shock symptoms very early and quickly.
3. Martial misfits; the "objector," who hates war but goes because he must and often malingers.
4. Concussion cases.
5. Cortical injury, a few of which get into the shell-shock group by mistake.
6. Cases of hysteria who show the major and minor symptoms of hysteria as in civil life.

From this brief outline on classification and definition, it can readily be seen that the term "shell-shock" is a blanket diagnosis to cover all the traumas and disorders of the central nervous system without visible injury, occurring in modern warfare. The term is a poor one, and Eder,[6] in his latest book, has used the title, "War-Shock: The Psycho-Neuroses in War." He markedly limits himself, however, by defining "war-shock" as "hysteria occurring in a person free from hereditary or personal psychoneurotic antecedents, but with a mind more responsive to psychical stimulus than the normal." Such a narrow definition seems to me unpractical, as many cases other than these must be treated as shell-shock in hospitals devoted to the care of the neuroses of the war. An expression much employed lately is "war-strain," but this is lacking in not emphasizing the dominant rôle of the central nervous system. As shell-shock is now so widely used, it does not seem practical to change it. G. Elliot Smith[7] did not use either "war-strain" or "war-shock" in his book on "Shell-Shock and Its Lessons," and preferred "shell-shock" "as a popular but inadequate title for all those mental effects of war experience which are sufficient to incapacitate a man from the performance of his military duties." A new and excellent classification by Hurst[8] is too long to reproduce here. It is, by far, the best one that has been made.[9]

---

* Read at the staff meeting, Boston Psychopathic Hospital, Oct. 17, 1917. The contents of this paper are based on observations made in England from May, 1916, to February, 1917, under grant of a Moseley Traveling Fellowship from Harvard University. Indebtedness is acknowledged to Sir William Osler and Dr. Frederick W. Mott for their kindness in making these observations possible.

PREDISPOSING CONDITIONS TO SHOCK

It has been found that in a large majority of cases of shell-shock the patients have a neuropathic tendency or inheritance. Some of Mott's patients "gave a history of either previous nervous breakdown or of a timid disposition, easily frightened, emotional, or afraid of the sight of blood; in a few, the fact was elicited that they had a fright in early childhood and that this recurred in dreams." In a case reported by Feiling,[10] the boy ran away from school at 13 because he was "tired of it," and also worked at various trades, at none of them apparently with any very marked success. In one of the best of the articles on shell-shock, Forsyth[11] says, "In all cases coming under the writer's notice with symptoms which were more than mild and transitory, a history of some earlier nervous trouble, slight or severe, was forthcoming." In twelve consecutive cases the following notes were elicited:

Nervous breakdown two years before.
Highly nervous and irritable.
Often depressed; worries over things.
Longish periods of depression.
Always been shy; still shy, though middle-aged.
Nervous breakdown four years ago.
Self-conscious.
Very depressed; worries unnecessarily.
Of nervous temperament.
Intensely self-conscious; married, but sexually impotent.
Highly strung and excitable since a child; violent tempered.

Later Forsyth says, "The occurrence of a definite neurosis is to be looked for only in psychopathic individuals, the onset representing the collapse of what is already psychically unsound."

Adrian and Yealland,[12] in a report on 250 cases, say:

> There are certain mental abnormalities which are present to some extent in nearly every patient. The majority of patients are below the average normal intelligence as judged by the Binet-Simon scale, and others who are more highly equipped prove to have an unstable history either personally or in the family.

Mott[13] again insists:

> Of even greater importance than the extrinsic conditions in the causation of military unfitness from exposure to shell fire are the intrinsic conditions, for if there is an inborn timorous or neurotic disposition, or an inborn or acquired neuropathic or psychopathic taint, causing a *locus minoris resistentiae* in the central nervous system, it necessarily follows that such a one will be unable to stand the terrifying effects of shell fire and the stress of trench warfare.

CONDITIONS AT THE TIME OF SHOCK

The conditions in the front-line trenches that put the soldier's nervous system "on edge" and sometimes are the sole factor in causing a war neurosis are intimated in a letter from an English officer to his mother, telling of his first experiences under shell fire:

> The shelling all day was awful. Before I had been in the trench three minutes, a bit of shrapnel made a clean cut in my breeches, only scratching the skin. The sights were awful, dead men all over the place, some half buried by shells. The ground and trenches had all been flattened out by our artillery fire, so there was hardly any shelter. I told the men to scratch themselves in with their entrenching tools, but it was simply a case of looking death in the face and waiting to be hit. Never for a moment did I expect to get out alive, as the shrapnel rattled all day long on my helmet, and of course the Boche might have counterattacked at any time. Many men got buried and had to be dug out. It was dreadful to see men's nerves give way and a man of 40 whimpering like a child and crying his soul out. Very catching this disease too, so I had to send him back. I never got into a smaller ball than I did that day, and of course the sights next one made eating impossible. When night came nerves got even worse, and there was hardly a man who was not shivering like a leaf. That day and night was a nightmare. It is the only time I ever felt the sweat of fear, but then it dropped off me in one continuous stream, as I thought in the dark my nose was bleeding.

From the foregoing note one gets a slight idea of active trench warfare. Mott[13] expresses it in this way:

> It must be obvious that through all the sensory avenues, exciting and terrifying impressions are continually streaming to the perceptual centers in the brain, arousing the primitive emotions and passions, and their instinctive reactions. The whole nervous system, excited and dominated by feelings of anger, disgust, and especially fear, is in a condition of continuous tension; sleep, the sweet unconscious quiet of the mind, is impossible or unrefreshing because broken or disturbed by terrifying dreams. Living in trenches or dugouts, exposed to wet, cold, and often (owing to shelling of the communicating trenches) to hunger and thirst, dazed or almost stunned by the increasing din of the guns, disgusted by foul stenches, by the rats and by insect tortures of flies, fleas, bugs and lice, the minor horrors of war, when combined with frequent grim and gruesome spectacles of comrades suddenly struck down, mangled, wounded, or dead, the memories of which are constantly recurring and exciting a dread of impending death or of being blown up by a mine and buried alive, together constitute experiences so depressing to the vital resistance of the nervous system, that a time must come when even the strongest man will succumb, and a shell bursting near may produce a sudden loss of consciousness, not by concussion or commotion, but by acting as the "last straw" on an utterly exhausted nervous system, worn out by this stress of trench warfare and want of sleep.

Forsyth[11] lays special stress on "the ghastly sights of carnage":

> These shake the self-control of all but the very strong, and when, as must often happen, a man sees his best friends killed or horribly mutilated, the anguish of his own feelings may unnerve him beyond control, even though, curiously enough, the effects may not be felt for hours or even days after.

From the psychologist's standpoint, the situation is interesting:

> At the time of the trauma, whether it is concentrated in a few moments or spread over days or weeks, the situation to be met derives its psychical importance from the fact that it involves the risk of death. Against this, the instinct of self-preservation rebels, employing as its weapon the powerful emotion of fear. And this, it is not superfluous to recall, is a natural emotion, and therefore ineradicable; its function, like that of its physical counterpart, pain, is protective, dictating an immediate flight from the danger arousing it. In face, therefore, of the prospect of sudden death, fear strains all its powers to enforce an escape, and it can be coerced only by a still more powerful effort of will.[11]

Just what happens at the precise moment of the shock is best shown by quotations from a few case histories. In one of Myers'[2] cases, the patient was not feeling afraid but "rather enjoying it" until the shells burst about him. While creeping under wire entanglements, some shells burst near him. "As he was struggling to disentangle himself from the wire, three more shells burst behind and one in front of him. Immediately after the shell had burst in front of him, his sight became blurred. At the same moment he was seized with shivering, and cold sweat broke out, especially round the loins." Another patient "was blown off a heap of bricks 15 feet high owing to a shell bursting close to him." Pemberton[14] relates the case of a sergeant of a battery of field artillery: "His gun was No. 1. A direct hit was made on No. 2 gun with a high-explosive shell, killing three men. I saw Sergeant ——— shortly afterward, and although naturally excited, he appeared otherwise normal. He went on working his gun until dawn next day, when he collapsed and was found lying across one of the disemboweled corpses." In Feiling's[10] case, a trench in which the patient was fighting was blown in and he was buried for twelve hours in a mass of mud and débris. Mott[3] gives the history of a captain as follows: "His whole company had been destroyed, and, while talking to a brother officer, the latter had half his head blown off by a piece of a shell." Another patient said: "There was something dropped into the trench. I think it was a shell. I felt myself go up into the air, but I cannot remember falling."

Forsyth[11] gives the following case to show how light trauma may be:

> The patient, after being for some weeks in France, where his battalion was completing its training, spent two nights, which were quiet ones, in reserve trenches. The following day, as his platoon was moving to the rear, a shell exploded close by, wounding several men, but killing none. He himself was unhurt, though he thinks some earth thrown up by the explosion may have struck his right arm. At any rate, on getting back to his billet, he found his right hand was weak, and the next morning he had lost the use of the right arm. When examined three weeks later, the limb was found to be paralyzed and showed marked involuntary movements, which had spread to the shoulder and right side of the neck. No organic cause of the condition could be found. Three months later the movements had ceased, but the arm was still weak.

RESULTS OF SHOCK: SYMPTOMS

1. *Loss of Consciousness.*—Most patients lose consciousness at the time of the shock, but many are only dazed or stuporous. The ones that die are usually unconscious from the time of shock. A condition of automatic wandering, like the fugue of an epileptic so vividly described by Marie, has been observed in some cases. Parsons[15] says, in a typical case "consciousness is lost for a variable time, but often not so far as to prevent automatic movements, so that the man may walk in a dazed condition to the dressing station."

2. *Amnesia.*—One of the most common symptoms of shell-shock is amnesia, or loss of recollection. Very few patients lose consciousness for anything but a short time, and the memory of many of the events during most of the period of trauma may be brought out in various forms of treatment. The temporary amnesia may be very severe and even complete. Mott[3] gives the history of a man who was blown up by a shell and who could not recollect any recent or past events. He did not recognize any coins or even his own written name. He rapidly improved and recovered completely. One of Myers'[16] cases is an example of retrograde amnesia:

> A private was found wandering in a neighboring village, clad only in his shirt and socks. "He was unable to give his name, regiment, or number. He thought his age was between 20 and 30. I tried him with various Christian names, but he replied that none of them seemed familiar to him. He could remember two men finding him as he was strolling on the outskirts of a village, and could describe everything that had occurred to him since then. There was no means of identifying him, and his past was a complete blank; he could recall nothing, for instance, of the events of his childhood."

Mott[3] gives another remarkable case, the treatment of which I shall give later in this paper. He writes:

> The patient's mind was a complete blank, and this condition was reflected in a dazed, mindless, masklike expression. When asked where he lived, he said, "W——"; he did not know it was in the West Riding. He did not know the address of his home; and when shown a letter from his father with the address on the top, he did not recognize it or his father's handwriting. When shown a photograph of his home, with a group of his father, mother, and three brothers in front of it, he maintained the same wondering, dazed expression, and failed to recognize the nature of the picture. His father had heard from a comrade that he had been buried by the explosion of a shell in the trench; that he had been unconscious for some time and lost his speech.

3. *Motor and Sensory Changes.*—Paralysis and disorder of gait are common symptoms. In 250 cases with some objective disorder, Adrian and Yealland[12] found 37 cases of monoplegia of the arm or leg, 46 of paraplegia, 16 of hemiplegia, and 18 of disordered gaits. The suggestion of an external injury is usually found in the history of these patients. The man who has fallen on his shoulder will have a monoplegia of the corresponding arm. Injury to the back often precedes paraplegia. The reflexes are normal or there may be an increase in knee-jerks with a spurious ankle-clonus. I cannot find that a positive Babinski sign has been reported in a purely functional case. The overaction of antagonistic muscles is quite remarkable, especially noticed in relation to gait. Batten[17] relates a case as follows:

> When first admitted and asked to walk, the patient grasped the top of the crutches and pulled the body up by the strength

[14] Pemberton: Lancet, London, 1915, **1**, 967.

[15] Parsons: Lancet, London, 1915, **1**, 697.

[16] Myers: Lancet, London, 1916, **1**, 65.

[17] Batten: Quart. Jour. Med., 1915-1916, **9**, 73.

of his arms; he then placed each crutch alternately forward, allowing the whole weight to fall on the advanced crutch, and would advance the legs synchronously with the crutch. Later, when taught to walk in the walking-machine, he would support the weight of the body on the hands, dragging the hindmost leg forward against a resistance produced by placing all the antagonistic muscles into forcible contractions. At a later period he walked without the machine, but with the hinder leg as if it were glued to the ground, from which it could only be moved by the most violent tugging efforts.

The direct opposite of the glued-to-the-ground foot is the dancing tremor, in which the patient walks as if the legs were on springs of coiled wire.

The paralyses differ in no way from the hysterical paralyses of civil life. Extensive paralysis is the usual thing, a whole arm or leg. They are often associated with sensory changes. Myers[18] has made a special study of these, finding various disorders of cutaneous sensibility in about 25 per cent. of his patients. Mott[3] found in severe cases of shock "loss of sensibility to all forms of stimulus, pricking, heat and cold, and touch, also of deep sensibility, pressure of muscles, movement of joints, and bone sensibility to vibration of tuning-fork. Hyperesthesia is even more common than anesthesia, and even the lightest touch gives rise to apprehension and movement of withdrawal in severe cases."

Tremors and coarser rhythmic spasmodic movements are an extremely common symptom. Mott[3] gives an example of a gunner blown up by a big shell who was amnesic for fourteen days. He says: "When I examined him he was sitting in a chair; legs, hands, and jaw were in continuous coarse rhythmical tremors like those of paralysis agitans, which became exaggerated when he was spoken to. Every now and again he starts and looks upward and laterally, as if he feared a shell would drop on him." Fine tremors like those of exophthalmic goiter have been noted, and also tremors of the intention type; but most of them were coarse rhythmic tremors like those of advanced paralysis agitans. In one of Mott's cases, a former pugilist was terrified by the explosion of bombs dropped by a Zeppelin and "developed a curious tic, which took the form of jerky purposive movements of the shoulders and head, as if to avoid a blow, and facial grimaces such as a pugilist might assume in a fight."

4. *Dreams, Terror and Mental Changes.*—In shell-shock, the patients often suffer from terrifying dreams. These are associated with the manifestations of fear, such as terrified facial expressions, cold blue hands, feeble pulse and respiration, sweats and tremors. These dreams often take on the form of nightmares, during which a soldier will go through the pantomime of some terrible experience at the front. I have seen men stand up in bed, sweating and pale, continually shouting epithets at the invisible enemy, go through the pantomime of a charge "over the top," and a hand-to-hand or bayonet attack on the enemy. Mott[3] gives a case as follows:

> A captain, aged 20, was admitted under my care in a state of restless delirium; he moved continually in the bed, sat up, passing his hand across the forehead as if he were witnessing some horrifying sight, and muttering to himself; yet, when interrogated, he answered quite rationally. This motor delirium I associated with the continuous effects on the conscious and subconscious mind of the terrible experiences he had gone through.

Sometimes the terror leads to mania:

> A young man, aged 19, was admitted, suffering with shock due to emotional stress and shell-fire. He suffered with terrifying dreams, and after he had been in the hospital a short time, he developed sudden paroxysmal attacks of maniacal excitement. One afternoon he had been helping as usual in the kitchen, and then he went and lay down on his bed and apparently went to sleep; he suddenly awoke with a startled, terrified look, became flushed in the face, sweated profusely, and made for the door as if to get away from some terrifying conditions. He was restrained with difficulty. He remained in this excited state, glaring rapidly from side to side, giving one the impression that he was suffering from terrifying hallucinations of sight and hearing, although he would make no response to interrogation. He did not recognize his wife, the doctors, or the sisters. Once when I, accompanied by two medical officers in uniform (strangers), came up to speak to him, he became violently agitated, as if some terrifying conditions had been aroused by the sight of the uniforms; the face was flushed and he sweated so profusely that the perspiration dripped in a stream off his nose. The attacks would last from a few hours to a few days; they came on quite suddenly, like an epileptic fit, and often without any apparent cause. It may be mentioned that there was no obtainable history of epilepsy or insanity in the family. The case rather suggests the psychic equivalent of epilepsy in the attacks.

Mott noticed other points of interest in his patients. Many complained of a falling or sinking feeling; often in their dreams, patients were heard to cry out and would awake to find themselves in a cold sweat; some officers gave commands to their men and urged them on to battle; and some performed the pantomime of raising the gun to the shoulder and pulling the trigger.

The revival of old associations in shell-shock dreams is not uncommon. In one of Mott's cases, the patient would dream of meeting a leper in a mine passage. He had been alarmed previously by a leper in a South African campaign. A single predominating incident may be repeated again and again in these terrifying dreams. A soldier who had seen a legless body of a comrade at the front had many dreams in which a legless body was always the central figure.

5. *Special Sense Disturbances.*—(*a*) Vision: The usual disturbances are photophobia, with or without blepharospasm, "smoky vision," diminution in the visual fields, and amblyopia. The photophobia is not usually a serious or persisting symptom; "smoky vision" may last for months. Diminution of visual fields alone is common. Patients with amblyopia usually go to special hospitals. The first and best cases recorded are those by Parsons[15] early in 1915. Functional blindness is more common than deafness, loss of smell or taste. "On examination, it is found that there are intense blepharospasms and lacrimation. The lids are opened with great difficulty, and examination of the eyes is almost impossible in the early stages." The man is struck blind instantaneously. In two to three weeks blepharospasm diminishes. "The fundi appear to be absolutely normal. The pupils react to light, though in some cases the reactions are sluggish, and sometimes one pupil differs from the other, being larger or more sluggish in its reaction. By this time probably some restoration of sight has occurred, light is perceived and large objects may be distinguished. As improvement occurs, the patient manages to grope about, usually with his hands outstretched before him, but it is noteworthy that he does not usually stumble against objects in his path. As soon as it is possible to take the fields of vision, it

---

[18] Myers: Lancet, London, 1916, 1, 608.

is found that they are markedly contracted, and that indeed to a degree which seems scarcely consistent with the avoidance of obstacles in walking. The recovery of vision is slow, but eventually it always seems to be complete."

In Pemberton's[14] case which I mentioned before, of the sergeant who suddenly collapsed twelve hours after seeing the gun-crew next to his hit, the amblyopia and contraction of fields was marked when first seen. There were many sensory and motor disorders, also.

(*b*) Speech: The speech defects most commonly noted are mutism, aphonia, stammering, stuttering and verbal repetition. Mutism is most common—about one in twenty, according to Mott. The patients cannot produce any audible sound; there is no sound when they attempt to laugh, try to whistle or cough. Most of these patients can write. "Many who are unable to speak voluntarily call out in their dreams expressions they have used in trench warfare and battle. Sometimes this is followed by return of speech, but more often not." Mott[3] continues, "This mutism is due to emotional shock; it is a psychic rather than physical trauma, in my judgment, for it in no way differs from the description of hysterical mutism thus given by Bastian." Anesthesia of the pharynx has been noted. Some cases will be quoted later, in the consideration of treatment.

(*c*) Hearing: Deafness often accompanies mutism or aphonia, causing the condition of functional deaf-mutism. "It is not at all infrequent for a man to be deaf on one side and not the other, and the history often shows in these cases that a shell has burst on this side of the man. Auditory hallucinations are not uncommon, and the patients complain of hearing the bursting of shells, of the noise of shells coming, of bullets whizzing, and of whistles blowing. Hyperacusis, or extreme sensibility to sound, is a common and very troublesome symptom, making the patient miserable and apprehensive." Mott found that many relapses occurred during a Zeppelin raid (on London), and one man, "a sergeant who had been a professional pugilist of great renown, suffered extremely, so that the noise of the click of billiard balls irritated him to such a degree that he would protest forcibly against the game continuing. His fellow patients found that they could easily cause him to flee by taking their slippers off and banging them on the ground sufficient to produce a sharp loud noise."

(*d*) Taste and Smell: Both are often affected, but owing to the difficulty of an examination which is so largely subjective, they are often omitted from the case reports. No very definite data could be obtained about them.

6. *Cardiovascular*.—"Patients often complain of palpitation, breathlessness on exertion, and precordial pain. There may be physical signs of dilatation and tachycardia. The pulse is often small and increased in frequency; the blood pressure is never high. It was often below 110, and never above 135. The hands are frequently blue or mottled and cold; and often there is cold, clammy sweating of the palms. The surface temperature may be very low; in one case it was only 16 C." (Mott[3]). Most of the patients with marked cardiac symptoms go to special hospitals. The complaints of these patients are: breathlessness, pain, giddiness, palpitation, and exhaustion on exertion. There are no physical signs of structural change in the heart. These are the cases of "irritable heart" that have received so much attention by Dr. Thomas Lewis and his colleagues at the Military Hospital, Hampstead, England.[19] In the broad sense these cases come under "shell-shock," as they are certainly functional disorders of the nervous system that are peculiar to modern warfare.

The vasomotor conditions are quite noticeable. Osler mentions the "men with unstable vasomotors" as unfit for the trenches. Excessive flushing and dermographia are quite commonly seen.

Headache is often a prominent symptom. Mott[3] says:

> The commonest situation for the maximum pain is the occipital region and the back of the neck; it is often described as a tight compression, like a helmet—the helmet of Minerva. The pain may be in the frontal region over one or both eyes, over the vertex, in one or both temples, or at the back of the eyes. The pain is variously described as burning, stabbing, or a heavy, dull, dizzy feeling, a feeling like a tight hat, or a red-hot wire being run through the temples. It is worse at night, especially upon lying down and trying to sleep.

NEUROPATHOLOGY

The neuropathology of shell-shock has received scant attention in the literature except for the work at Dr. Mott's laboratory. The reasons are quite obvious, as very few patients died at the hospitals except by chance of intercurrent disease, and those that die on the field are seldom examined postmortem. In the last year, however, more provision has been made for necropsies at or near the front, and by arrangement with the Royal College of Surgeons, London, certain brains are being sent back, properly preserved for future study. Dr. Mott[20] has been fortunate enough to secure a few of these, and his findings are of great interest. He first noticed the marked similarity between the brain of a soldier dead from shell-shock and the brain of a man dead from carbon monoxid poisoning. His study of carbon monoxid poisoning before the war led him to think that the main postmortem findings were extensive capillary hemorrhage in the brain, especially in the corpus callosum, the internal capsule, cerebral peduncles and centrum ovale.[21] Two cases were from carbonyl of nickel works. There was a case of suicide by illuminating gas. In the first case of shell-shock, a man had been buried by a shell blowing in a parapet, and had died two days later. No visible wounds were found on the body. Throughout the white matter of the centrum ovale, and especially in the corpus callosum, were multiple punctate hemorrhages. Mott[3] says: "This appearance to the naked eye corresponds to that which I have described in carbon monoxid poisoning. The same microscopic appearances were observed as those seen in coal gas (CO) poisoning, only the hemorrhages were more extensive." Apparently the fatal cases are the gas cases, as Mott has found the same appearance in later brains. These are the true cases of shell-shock with burial that form a very small part of the vast number of cases in men who return from the front with symptoms of a neurosis. Whether these also may have minor brain hemorrhages is problematical, but we may feel certain that many men who never got within the range of shells and yet develop brain symptoms probably have no such gross pathologic lesions. Most neurologists believe with Wilt-

of his arms; he then placed each crutch alternately forward, allowing the whole weight to fall on the advanced crutch, and would advance the legs synchronously with the crutch. Later, when taught to walk in the walking-machine, he would support the weight of the body on the hands, dragging the hindmost leg forward against a resistance produced by placing all the antagonistic muscles into forcible contractions. At a later period he walked without the machine, but with the hinder leg as if it were glued to the ground, from which it could only be moved by the most violent tugging efforts.

The direct opposite of the glued-to-the-ground foot is the dancing tremor, in which the patient walks as if the legs were on springs of coiled wire.

The paralyses differ in no way from the hysterical paralyses of civil life. Extensive paralysis is the usual thing, a whole arm or leg. They are often associated with sensory changes. Myers[18] has made a special study of these, finding various disorders of cutaneous sensibility in about 25 per cent. of his patients. Mott[3] found in severe cases of shock "loss of sensibility to all forms of stimulus, pricking, heat and cold, and touch, also of deep sensibility, pressure of muscles, movement of joints, and bone sensibility to vibration of tuning-fork. Hyperesthesia is even more common than anesthesia, and even the lightest touch gives rise to apprehension and movement of withdrawal in severe cases."

Tremors and coarser rhythmic spasmodic movements are an extremely common symptom. Mott[3] gives an example of a gunner blown up by a big shell who was amnesic for fourteen days. He says: "When I examined him he was sitting in a chair; legs, hands, and jaw were in continuous coarse rhythmical tremors like those of paralysis agitans, which became exaggerated when he was spoken to. Every now and again he starts and looks upward and laterally, as if he feared a shell would drop on him." Fine tremors like those of exophthalmic goiter have been noted, and also tremors of the intention type; but most of them were coarse rhythmic tremors like those of advanced paralysis agitans. In one of Mott's cases, a former pugilist was terrified by the explosion of bombs dropped by a Zeppelin and "developed a curious tic, which took the form of jerky purposive movements of the shoulders and head, as if to avoid a blow, and facial grimaces such as a pugilist might assume in a fight."

4. *Dreams, Terror and Mental Changes.*—In shell-shock, the patients often suffer from terrifying dreams. These are associated with the manifestations of fear, such as terrified facial expressions, cold blue hands, feeble pulse and respiration, sweats and tremors. These dreams often take on the form of nightmares, during which a soldier will go through the pantomime of some terrible experience at the front. I have seen men stand up in bed, sweating and pale, continually shouting epithets at the invisible enemy, go through the pantomime of a charge "over the top," and a hand-to-hand or bayonet attack on the enemy. Mott[3] gives a case as follows:

> A captain, aged 20, was admitted under my care in a state of restless delirium; he moved continually in the bed, sat up, passing his hand across the forehead as if he were witnessing some horrifying sight, and muttering to himself; yet, when interrogated, he answered quite rationally. This motor delirium I associated with the continuous effects on the conscious and subconscious mind of the terrible experiences he had gone through.

Sometimes the terror leads to mania:

> A young man, aged 19, was admitted, suffering with shock due to emotional stress and shell-fire. He suffered with terrifying dreams, and after he had been in the hospital a short time, he developed sudden paroxysmal attacks of maniacal excitement. One afternoon he had been helping as usual in the kitchen, and then he went and lay down on his bed and apparently went to sleep; he suddenly awoke with a startled, terrified look, became flushed in the face, sweated profusely, and made for the door as if to get away from some terrifying conditions. He was restrained with difficulty. He remained in this excited state, glaring rapidly from side to side, giving one the impression that he was suffering from terrifying hallucinations of sight and hearing, although he would make no response to interrogation. He did not recognize his wife, the doctors, or the sisters. Once when I, accompanied by two medical officers in uniform (strangers), came up to speak to him, he became violently agitated, as if some terrifying conditions had been aroused by the sight of the uniforms; the face was flushed and he sweated so profusely that the perspiration dripped in a stream off his nose. The attacks would last from a few hours to a few days; they came on quite suddenly, like an epileptic fit, and often without any apparent cause. It may be mentioned that there was no obtainable history of epilepsy or insanity in the family. The case rather suggests the psychic equivalent of epilepsy in the attacks.

Mott noticed other points of interest in his patients. Many complained of a falling or sinking feeling; often in their dreams, patients were heard to cry out and would awake to find themselves in a cold sweat; some officers gave commands to their men and urged them on to battle; and some performed the pantomime of raising the gun to the shoulder and pulling the trigger.

The revival of old associations in shell-shock dreams is not uncommon. In one of Mott's cases, the patient would dream of meeting a leper in a mine passage. He had been alarmed previously by a leper in a South African campaign. A single predominating incident may be repeated again and again in these terrifying dreams. A soldier who had seen a legless body of a comrade at the front had many dreams in which a legless body was always the central figure.

5. *Special Sense Disturbances.*—(*a*) Vision: The usual disturbances are photophobia, with or without blepharospasm, "smoky vision," diminution in the visual fields, and amblyopia. The photophobia is not usually a serious or persisting symptom; "smoky vision" may last for months. Diminution of visual fields alone is common. Patients with amblyopia usually go to special hospitals. The first and best cases recorded are those by Parsons[15] early in 1915. Functional blindness is more common than deafness, loss of smell or taste. "On examination, it is found that there are intense blepharospasms and lacrimation. The lids are opened with great difficulty, and examination of the eyes is almost impossible in the early stages." The man is struck blind instantaneously. In two to three weeks blepharospasm diminishes. "The fundi appear to be absolutely normal. [18] Myers: Lancet, London, 1916, 1, 608.

on the hospital and its environment. At his beautiful institution outside of London, he has:

> Light airy wards, and day rooms for meals and recreation, plenty of single rooms for the isolation of cases that are troubled with noises or require special attention; and especially valuable are the baths, so that every soldier can get a warm or cold spray bath every day. The warm baths, and especially the continuous warm baths, are especially valuable for promoting the action of the skin, of relaxing the tired muscles, and by the soothing influences helping to induce sleep, so that less hypnotics are required to be employed.

In these ideal surroundings the patients are usually left to adjust themselves.

When indicated, mild suggestive and persuasive measures are used, as in the case of amnesia partly quoted. The story continues as follows:

> We heard from his father that he was a good musician, and I said to him, "G——, I hear you are a good musician," and I asked him if he could play the piano or sing; there was the same wondering, bewildered look, and he muttered something which was to the effect that he could not sing or play. Three days later I said, "Come, you can whistle 'God Save the King.'" He took no notice, but upon pressing him, he looked up and a glint appeared in his eyes, and he said "You start me." I whistled the first bar; he took it up and whistled it admirably. I then asked him to whistle "Tipperary," but he could not do it till I started him, and the same with several other tunes, but once started, he had no difficulty, and I recognized from the admirable intonation that he was, as his father described him, an excellent musician. I could not, however, that day get him to start upon his own initiative any one of the tunes he had whistled. The next visit, three days later, I observed that his expression had changed. He smiled when I spoke to him, and I recognized clear evidence of a mind that had partly found itself. He could not whistle by himself any of the tunes I had previously started him on when I called for them. [He relearned to play the piano by first having his finger held on the keys and a melody played.] The next time I came, he was able to play any music set before him. His associative memory and recollection of music were in advance of other associative memories. Thus, eight months after he had recovered his musical memory, he had very imperfectly recovered his memory of elementary facts regarding his profession as a land surveyor, and there was still a tendency to a vacant, mindless expression and prolonged reaction time as shown by delay and slowness in responding to questions, as if there were a difficulty in linking up the necessary associations.

Mott reports that about thirty-five cases of mutism have come under his observation, with recovery in all. Some of the recoveries take place under most amusing circumstances:

> In one case the patient "was sitting in his wheeled-chair playing baseball, at which he was quite good, when a runner overturned him; the sudden emotional shock and surprise made him exclaim aloud, and since then he has quite recovered speech." Strong faradic stimulation to the larynx in this patient had *not* resulted in phonation. Another patient "was in a punt and it was turned over, and he was capsized into the water, which made him shout out. Practically, he had been mute for more than eight months. He often shouted words in his sleep about trench warfare, so he must have had dreams but forgot them." This patient under the strong suggestion of removal of adenoids did not speak. In regard to a third patient, the following is told: "His fellow soldiers thought he ought to hear and speak, and they adopted energetic measures to make him shout out for help. Two of them leathered him with a slipper and then nearly throttled him. He struggled and shouted 'Stop it.'"
>
> One dreamed he was falling over a cliff, shouted out, and recovered his speech. A deaf-mute was heard to speak in his sleep. He was told of it by a comrade. He said, "I don't believe it."

Mott's summary of treatment is as follows:

> Be cheerful and look cheerful is the note that should ever be sounded to these functional cases. Sympathy should not be misplaced, although it should be shown to all these poor fellows who have a fixed idea of never recovering; it is not their fault, it is a real thing to them, and no one could be more grateful than these cases of functional nervous disability for cheery words. I use many of these cases that have recovered as object-lessons. I do not find hypnosis or psychoanalysis necessary or even desirable."

Forsyth[11] thus outlines his treatment:

> The only treatment during the acute stage comprises three items—physical rest in bed, mental quiet, and good food. A private room is best. "Noises of all kinds, indoor and out, are borne with intolerance and are harmful, especially if they are unexpected and even remotely recall the dreaded shell explosions." At first the patients should be left to themselves, without being disturbed by the taking of medical histories or conversation. "They must expect to pass restless nights with piercingly vivid dreams, for which even hypnotics are only palliative. Those with the mildest symptoms can safely be allowed to get up within a few days, gradually increasing this exertion, until perhaps in a week or a fortnight they can get away to the quiet of the country or the seaside; and in another six weeks they will probably be able, not indeed to return to the front, but to take up light duties at home."

Most patients need bed for three to four weeks or longer, followed by two or three months of quiet living. "Throughout the greater part of convalescence any indiscretion in the way of mental or physical exertion beyond the narrow margin of the patient's endurance at the time seems regularly to entail a setback out of all proportion to the extra effort."

The symptoms of depression of spirits, listlessness, taciturnity, desire for solitude, lack of confidence, poor appetite and sleeplessness are "best and most quickly relieved when the patient has been induced to talk freely of what is on his mind, the opportunity at the same time being taken to present his facts to him in their true light, together with the additional information he needs to form a just opinion of his conduct and to rehabilitate himself in his own esteem." Forsyth looks at the neurotic symptoms as in a case of everyday neurosis, a problem dealing with "the psychical development of the patient since childhood; and the further treatment must follow psychanalytical lines." A patient who has not been able to regain his self-control after three or four months is in need of extraneous help, that is, psychotherapy.

Rows'[26] treatment is along nonradical lines. He says that the patient's difficulty lies chiefly in the fact that:

> He has little or no insight into the nature and mode of origin of his mental illness. This insight can be provided by explaining to him in plain language the mechanism of simple mental processes, by enabling him to understand that every incident is accompanied by its own special emotional state and that this emotional state can be reawakened by the revival of the incident in memory. The patient will thus be led to see that it has been no gross disease and no supernatural agency which has disturbed him; he will be able to recognize the relation of cause and effect in the origin and development of his illness. When this relation is appreciated, both the patient and the physician will begin to realize that they have some ground in common. The physician should

---

[26] Rows: Brit. Med. Jour., 1916, 1, 441.

be prepared to give at least an hour for an interview, and in most instances several interviews will be necessary.

The value of psychanalysis as a form of treatment has caused much controversy in England. Adrian and Yealland[12] believe it to be very valuable as a form of treatment for the state of mind of the patient which has allowed a fixed idea to develop. The fixed idea itself that gives rise to the functional symptom or paralysis, loss of speech, etc., is best treated by suggestion, but at the basis of this is a state of mind that will not vanish by these methods. They say that the patient minus his symptoms "will always be liable to develop hysterical troubles in moments of emotional stress and exhaustion, just as a man with a malformed chest will be liable to attacks of bronchitis." This is borne out by the number of patients returned from the front with a remission of symptoms after apparent recovery. Psychanalysis, in their opinion, will "cure not only the hysterical symptoms but also the hysterical mentality." If the repressed desire is "unearthed and explained to the patient, the repressed conflict will vanish, and with it not only the hysterical symptom but also the state of mind which made this symptom possible." Practically it takes too long a period to use psychanalysis on the average shell-shock patient, and it can be used only in special hospitals. One must therefore treat symptoms during the war and leave this longer method for more leisure moments.

Eder[23] also thinks psychanalysis valuable but not usually expedient in war time. He, however, uses it "for purposes of diagnosis or with a view to helpful suggestion in most cases."

One of the most important problems in the early part of 1915 was the question of sending the apparently cured patients back to the front. Those that went back proved useless as soldiers in front-line trench duty, for they broke down again either on the way to France or soon after reaching the trenches. Forsyth's views are that "with an increasing experience of these cases a very strong doubt rises as to the judiciousness of sending any cases of nerve-shock, with few exceptions, back to the firing line." If the patient knows he will not return to trench warfare, he makes a more rapid recovery. Forsyth thinks that these patients should be kept in England on light duty because of the following points:

1. Their untrustworthy memory (one of the last symptoms to disappear), by leading them to forget to carry out orders or to forget when they have carried them out, may entail the miscarriage of plans.

2. Their example may infect those around them with irresolution or even worse.

3. When the strain becomes severe, they will almost certainly break down a second time.

The hospital building and its surroundings are important in the treatment of war neurosis. The English War Office has arranged two exceptionally fine hospitals for officers,[27] one on a quiet street in London, of thirty-three plain bedrooms with gray walls, without pictures or ornaments. Here the patients are received from France and given from three to four weeks of a modified Weir-Mitchell treatment of absolute rest in bed in quiet surroundings. When somewhat recovered, they are removed to a large country house, where they remain for six weeks or longer and receive the treatment that has been outlined above.

For the soldiers a complete series of hospitals has been inaugurated.[28] There are two "clearing hospitals" of 500 beds for all neurologic patients, including those with functional paralysis, disturbances of speech, amnesia, mutism, deafness, amblyopia, motor agitations, nervous debility, mild neurasthenia, simple mental confusion, anxiety psychoneurosis, simple mental depression, etc. The treatment here consists of rest, proper feeding, massage, electricity, baths, psychotherapy, simple suggestion and occasional hypnosis. From these two hospitals about 40 per cent. return to light duty, 20 per cent. are invalided, and 20 per cent. are transferred to special institutions.

Of these special institutions there are two of about 550 beds, mostly with single isolated rooms. No new patients are sent here, but only those transferred from the neurologic hospitals. Here are treated severe neurasthenia, mild psychoses, profound amnesia, epilepsy and mild primary dementia. The treatment consists of rest, proper feeding, recreation and massage. Psychanalysis is used in selected cases. About 40 per cent. of these patients return to light duty.

There are also two hospitals of 700 beds for certificable mental patients. From 10 to 15 per cent. of these return to light duty.

PROPHYLAXIS

What can the Medical Corps of the United States Army do toward the prevention of shell-shock? Obviously it must be checked at the recruiting station or in the cantonment camps before the men leave for France. There ought to be no question in the minds of the medical officers as to the advisability of checking this condition at the source, for no one who has seen the results of modern warfare on the unstable mind can do otherwise than urge such measures with his utmost vigor. It becomes the duty of each medical examiner to weed out from the recruits such men as are liable to shell-shock. By so doing, an enormously important advance will be made in our army, as judged by the experiences of the other armies of the Allies.

We have been strongly advised by Osler to check the enlistment of the neurasthenic. It is obviously difficult to pick him from the crowd, "as he may come up in good form" and be eager to go overseas. But it is not so difficult with the mentally deficient, the "queer stick," the "boob," and the butt of the practical jokers. He is soon observed and noted by both officers and men, and if he is singled out and talked with for five or ten minutes one ought to have no difficulty in deciding his fitness for active trench warfare. One ought also to look especially carefully into the past history of the depressed, the man who worries unnecessarily, the self-conscious, the shy, the high-strung, excitable man, the violent-tempered, the nervous, the timorous, the easily frightened, or the neurotic individual. Any or all of them may make poor first-line-trench soldiers. The task is a difficult one, but that in itself should not prevent our trying. What an advantage it would be to our army officers, and what a saving of life it would mean to our men, if the shell-shock patients could be eliminated from our forces that will fight overseas! Such utopia is probably impossible, but I feel confident that careful weeding out of the mentally unstable will certainly greatly reduce the numbers of shell-shock cases that are bound to appear in our casualty lists.

THE WILD RATS OF THE SOUTHERN STATES AS CARRIERS OF SPIROCHAETA ICTEROHEMORRHAGIAE *

JAMES W. JOBLING, M.D.
AND
A. A. EGGSTEIN, M.D.
NASHVILLE, TENN.

In order to preserve the health of the large number of men now being trained in the various cantonments, it is essential that we recognize the sources of infections to which they may be subjected. This applies particularly to infectious jaundice, a disease with which many of the medical officers and civilian physicians are not familiar.

Infectious jaundice is not a new disease, as Cleghorn reported an epidemic in Minorca in 1745, and Larry, while he was with Napoleon in Egypt, in 1800, observed an epidemic near Cairo. In the Civil War, 22,509 cases were reported among the Northern troops, with 161 deaths. Epidemics were also observed among the Bavarian troops in the France-German War in 1870, and the disease has been epidemic for many years in Japan. A small epidemic was reported in North Carolina in 1900, and Barker described a series of cases which he observed in the city jail in Baltimore, in 1909. The case which we observed here in Nashville was in the service of Dr. O. N. Bryan, in the Vanderbilt University Hospital, and is the first so far as we can discover that has been reported from this section of the United States.

In view of the trench training that is now being given to the soldiers at the various Southern camps and the possibility of their being subjected to infection from the rats that frequently infest these places, we thought it important to determine whether or not the wild rats of the South harbor the *Spirochaeta icterohemorrhagiae*. The present report deals with the results of this investigation.

The etiology of infectious jaundice has been attributed to many bacteria, but none of these has been shown to bear a definite relation to the disease. In 1914, Inada, Ido and their associates[1] succeeded in transmitting the infection to guinea-pigs by intraperitoneal injections of blood taken from patients suffering from the disease, and noted the presence of large numbers of spirochetes in the blood and in the organs of these animals. Later, the same observers found a similar spirochete, which they termed *Spirochaeta icterohemorrhagiae,* in the blood and organs of human patients dying from the disease. During their investigations, made to determine the source of the infection, they found that wild rats harbor the *Spirochaeta icterohemorrhagiae,* and that the majority of persons affected were those whose occupation brought them into more or less intimate contact with places infested with these animals. The work of the Japanese observers has been confirmed in various parts of Europe, particularly in the war zone, and Noguchi,[2] in this country, found that the spirochetes were present in the wild rats in New York City.

With the object of determining whether or not the wild rats of this locality harbor the *Spirochaeta icterohemorrhagiae,* we examined a large number caught in different places in Nashville.

The rats were alive when brought to the laboratory. They were killed with chloroform, the hair was moistened with alcohol, and the kidneys were removed with precautions to insure asepsis. One kidney from each animal was made into an emulsion in saline solution and injected into the peritoneal cavity of a guinea-pig. The remaining kidney was prepared for microscopic examination. Levaditi's method was used to demonstrate the spirochetes in the organs.

More than a hundred rats were examined, and of these at least 10 per cent. harbored the *Spirochaeta icterohemorrhagiae.* These rats were obtained from different parts of the city, and so far as can be determined the various localities have given about the same proportion of infected animals.

The guinea-pigs that developed the disease usually died from the twelfth to the fourteenth day following inoculation. Jaundice of the sclera and of the mucous membranes became very marked before death, and postmortem examination revealed a yellowish discoloration of the subcutaneous tissues and of nearly all the internal organs. In addition, there were many small hemorrhages scattered through the subcutaneous tissues, and particularly in the inguinal and axillary regions. The spirochetes were demonstrated in the urine with the India ink method, and were readily found in the kidneys from the infected rats and in those from the inoculated guinea-pigs that developed the disease. These sections were stained by Levaditi's method. The virulence of the organism increases rather rapidly, as shown by the short duration of the disease when material from infected guinea-pigs is injected into others. These animals die in about half the time required for those inoculated direct from the rats.

From the foregoing it will be seen that about 10 per cent. of the wild rats of this community harbor the parasite causing hemorrhagic icterus, and as Noguchi has shown that the rats about New York City are also infected, it is probable that similar conditions apply in many sections of this country. The importance of these observations becomes more evident when we consider the trench training that is now being given to American soldiers in the various camps. Here we have duplicated in many ways the conditions that make possible the large number of cases now being reported in France and Italy, and our demonstration that the rats of the South harbor the parasites of this disease makes it obvious that all possible means should be used in the camps to eradicate these pests. It has been shown that the virulence of this organism for guinea-pigs increases rapidly when transmitted through several series of these animals, and we must not forget that the same thing may occur when the organism becomes acclimated to human beings. This would seem to explain the high mortality of 38 per cent. noted in Japan, where the disease is more prevalent; while in Europe, where fewer cases have been observed, the mortality is much less.

Insurance for Parturients.—The Italian government, it is announced, has arranged a system of insurance for parturients in wage-earning families. At childbirth each mother receives 40 lire ($8) from a fund to which for each person insured the state gives 12 lire annually, the employer 1.25 lire and the insured 1 lire.

THE HEART'S ACTIVITIES

The movements of the mammalian heart are so rapid and the performances of its various parts follow each other in such rapid succession that they call for delicate methods of registration and study. Many of our readers can easily recall the variety of recording apparatus that furnished the data in the early work of Chauveau and Marey, and in the investigations of many of their successors. Recording levers and tambours played a conspicuous part. Gradually they were made lighter and more delicate; yet such mechanical devices left much to be desired.

The introduction of electrocardiography has marked a decided step in advance. The real starting point was perhaps represented by the investigations of Burdon-Sanderson and Page in 1878 with the capillary electrometer on the tortoise heart. Waller in London initiated this mode of investigation on man a few years later; but, as Lewis[1] remarks, it was in the present century that Einthoven, in Holland, perfected an instrument which, on account of the facility of its working and the precision of its movements, has enabled us to unveil much that was formerly mysterious. This instrument is the string galvanometer, and its construction must rank as an outstanding milestone in the study of the questions that we are considering. The electric current and the sensitive photographic plate have contributed in an unanticipated way to the solution of many difficult problems in the physiology and pathology of the heart.

What are some of the acquisitions to science derived through these studies, particularly as they have been combined with elaborate investigations of the minute morphology of the heart? Lewis, himself a skilled experimenter in this field, offers this explanation for the development of two sets of chambers in the heart: an upper one "frail and thin-walled"; the lower "sturdy and massive." The function of the auricle, he concludes, is not to fill the ventricle, as is so commonly taught in elementary classes. The blood pumped from auricle to ventricle at the end of the heart's diastole is only a fraction of its full content. The function of the auricle is to save the veins from overdistention. During a third of the ventricular cycle, during the period when the ventricle is pouring blood into the body, the circulation is completely obstructed at the auriculoventricular orifices. Yet the blood flow in the veins continues; the flow goes on into the expanding auricles. The mechanical function of the auricle is that of a reservoir, to catch and hold the content of the stream when a dam is thrown across it. It wants little strength for this task; its walls must stretch easily; they have to pump against a low resistance; the muscle layer is therefore thin.

The spread of the contraction wave from the mouth of the great veins to the auricular mass as a whole, Lewis continues, is expedited by the central position of the node from which the wave starts, by the architecture of the muscle bands that radiate from it in all directions, and, lastly, by the relatively high rate of conduction that auricular muscle possesses.

In traveling through the auriculoventricular node, the contraction wave meets a long delay in its progress while the auricle is emptying itself. Thereupon it spreads to the bundle, a structure of fibers endowed with conducting fibers of the highest order, with the result that all parts of both ventricles are thrown into contraction with the closest approach to simultaneity. Hence, too, the mechanical advantage of the ventricle as a driving power.

THE EFFECT OF RANK ON THE DUTIES AND RESPONSIBILITIES OF THE MEDICAL OFFICER

The importance of the medical officer in the armies engaged in war, as indicated by the rank and authority given him, is less highly esteemed in this country than in any other, including both our allies and our enemies. Medicine has accomplished great triumphs in the armies of Europe. Under unprecedentedly difficult conditions, sanitation has been so ably maintained that both morbidity and mortality from the infectious diseases are less today in the military than in the civilian population of the warring nations. In the British Army, 80 per cent. of the wounded have been returned to duty. The number of hospitals in France reaches into the hundreds, and for the most part their equipment is excellent. Scientific laboratories are carrying on practical research investigations. Chemists are finding antidotes for the multitudinous poisonous gases turned on by the Germans, and are discovering new compounds to be used offensively. Within twenty-four hours after the first discharge of chlorin by the Germans, not only had the nature of the gas been determined and an antidote found, but protective masks were being made; and within ten days the Germans were being treated with the more deadly phosgen. Indeed, scientific studies made at the front saved the armies of Great Britain and France from complete annihilation. Rehabilitation hospitals in which the badly injured are supplied with artificial limbs and other devices are working successfully and converting the apparently hopelessly maimed into productive, self-supporting citizens. In fact, these institutions constitute one of the great triumphs of military and conservative medicine. Every wounded and sick soldier can be instantly located and his condition reported to his friends. In this way the discontent arising from anxious waiting for news is avoided. There has been no breakdown in the medical service in the great armies of Europe, as has been the case so often in the past and with us in 1898. When a son is killed in battle, parents seek and find consolation in the proud knowledge that he has died fighting for his home and his country; but when he is wounded or sick and dies from neglect, there is no consolation, and in the most patriotic soul a bitterness against those in authority develops.

---

[1] Lewis, Thomas: Upon the Motion of the Mammalian Heart, Croonian Lecture, Proc. Roy. Soc., B, 1917, 89, 560.

All this and much more might be said concerning the efficiency of the medical service of our chief allies. What is the explanation of its efficiency? The answer is that the medical officer is given support backed by rank and authority. A line officer in the British Army hesitates a long while before he rejects the advice of his medical colleague, because that colleague has rank and authority commensurate in some degree at least with his own, and is recognized as his superior in the special line of work. Compare this with the record of the congressional inquiry into the conduct of the War Department in the war with Spain, when, according to his own testimony, the commanding officer at Chickamauga in 1898 ostentatiously drank from a well condemned by his medical officer, while his hospitals were filled with typhoid fever patients. We have gone into this war with the medical officer invested with no more authority than he had in 1898. Is it unreasonable to ask if we are to repeat the experiences of that time? However, we are told that the line officer of today is much wiser than his predecessor of twenty years ago, and since he makes this statement himself, we must give it credence. We certainly hope that it is true. It is the duty of the medical profession to protest against this condition. The medical men of this country are not slackers, as is shown by the fact that more than one seventh of their total number have voluntarily offered their services to their country, notwithstanding the failure of those in authority to give the reasonable recognition asked. We have asked for increased authority, and in the Army this can be secured only by high rank, because when a medical man goes into the service the government puts its stamp on him just as it does on the coin of the realm; and 30 cents will not buy a dollar's worth of anything. So far the protest has fallen on deaf ears.

Medical men will play the game and do their duty, whatever may be the verdict in this matter; but it should be clearly understood that they are going into the game under a heavy handicap. They will do the best they can; but if discontent should arise from poor or poorly prepared rations, if respiratory diseases prevail as the result of overcrowding, if pneumonia becomes widespread because barracks are not heated and soldiers are not warmly clothed and amply provided with blankets — if all these things happen, the medical officer will continue to do the best he can under the conditions, but he will not be responsible for the conditions.

PULMONARY VENTILATION AND THE CARBON DIOXID OF THE BLOOD

The renewal of the air in the lungs, with which the blood exchanges its gaseous constituents, is brought about by muscular movements, which are under the control of the nervous system. When it was discovered that the functioning of this regulatory mechanism was in large part dependent on the chemical composition of the blood reaching the respiratory center, the natural tendency was to ascribe the stimulation of the latter to a fall in the oxygen tension in the circulatory system. It is now understood, however, that until the oxygen tension falls very decidedly, no noteworthy change in the ventilation of the lungs takes place so long as an increase of carbon dioxid tension is prevented. The classic investigation of Haldane and Priestley, reported in 1905, has demonstrated in a convincing way that the total volume of air sent in and out of the lungs in a unit of time by the respiratory movements is regulated by the carbon dioxid tension of arterial blood, which is the same as that of the alveolar air of the lungs. Subsequently, Haldane and his co-workers showed, in 1913, that the alveolar oxygen pressure can be varied within wide limits without sensibly affecting the excitability of the respiratory center to carbon dioxid.[1]

Whether certain types of clinical dyspnea are due, primarily, to retained carbonic acid, rather than to other acids formed in metabolism, has frequently been asked by those engaged in the study of acidosis in its relation to pathologic symptoms. The difficulties in answering this question have been due in part to the lack of suitable methods for the detection of very small deviations from the normal in the composition of the blood. Indirect methods, such as the determination of the alveolar carbon dioxid and the total carbonate concentration of the blood, have become popular in the study of the interrelations between the composition of the blood and the respiratory exchange. In the physiologic laboratory of the Western Reserve University School of Medicine, Cleveland, Scott[2] has noted in that ammonia is liberated in the muscle or other body cells and carried to the liver to undergo there a final synthesis to urea. One step in the exclusion of conflicting hypotheses lies in direct observations on the possibility of urea formation by self-contained enzymes in muscle. Such an investigation has been undertaken by Hoagland and Mansfield[1] in the Bureau of Animal Industry at Washington. The results of their studies of the products of autolytic change in aseptically removed portions of muscle tend to show, as they themselves express it, that urea formation is not an important function of muscular tissue. In view of the well established fact that the liver plays an important part in the formation of urea in the body, they add, these findings lend support to the view that urea production is chiefly a function of that organ. In the light of current evidence they give added weight, though in a very indirect way, to the view of Van Slyke and his co-workers that the liver plays the chief part in the breakdown of the amino-acids, without denying to other tissues the possession of similar power of promoting metabolic change.

Current Comment

THE ARMY HOSPITALS OF FIFTY YEARS AGO

At the present time when every noteworthy contribution of modern medical science may be expected to be put to the test of usefulness in the plans of the Army medical organization, the task of meeting a great emergency successfully is almost certain to leave unfulfilled possibilities exposed to the ubiquitous critic. To those on whom devolves the responsibility for the major part of the effort of suddenly providing for the sanitary and medical needs of a vast group of fighting units it may be comforting, if not helpful, to learn something of the fire of criticism through which the United States Army has passed in former days in respect to its barracks, hygiene and hospitals. A notable instance has lately been described by Dr. Fielding H. Garrison[2] of the Surgeon-General's Office in a review of the scientific work of the late Dr. John Shaw Billings. In 1870 and 1875, Billings made two reports to the Surgeon-General which have become classic, as far as our military establishment is concerned. In a drastic criticism of the barracks and hospitals of "the best fed and worst housed army in the world," Billings described the pictures of United States Army hospitals in the report as "simply inserted as ingenious modes of 'how not to do it'." There is vigorous opposition to the false economy which results in "a saving in boards and brick at the expense of the health of the soldier." Of more immediate interest today, however, is the substance of the constructive advice for improving the health and personal well-being of the enlisted man. Garrison has thus summarized Billings' suggestions, given in 1875: Bath tubs and shower baths, abundant space and good ventilation in quarters, a ration at least 25 per cent. in excess of what is required, plenty of ice at southern posts, lime juice and baking powder for scouts, canned tomatoes when fresh vegetables are not available, are recommended as novelties; and it is especially urged that the chief cook at a post should be a permanent detail, in place of the custom at that time of changing company cooks every ten days; that schools for instruction of cooks should be established at recruiting stations, and that a manual of cookery, with dietetic tables and culinary directions for all climates and seasons should be prepared. The report concludes with timely observations on the ventilation, hygiene and avoidance of infection in the military hospitals. Today the "novelties" here recommended have become the "staples" of hospital routine; but there is an ever-recurring abundance of new problems that demand novel solutions, and perhaps some old defects that deserve exposure. To these a new generation of trained scientists and devoted men is giving its best intellectual efforts.

ADULTERATED IMPORTED DRUGS

In times of stress, it is often feared that our food and drug laws will not be vigorously enforced. It is gratifying, therefore, to note the regulatory announcements of the Department of Agriculture[1] concerning action against and detention of certain drug imports. A recent issue reports that examinations of samples of belladonna root, *Atropa belladonna* L., disclosed adulteration with roots of yellow dock, *Rumex crispus* L. Some importations of cantharides (Spanish flies), *Cantharis vesicatoria*, had been adulterated with "so-called Chinese blister flies belonging to a species of *Mylabris*." The department found cinchona barks offered for entry under names recognized in the U. S. Pharmacopeia, but deficient in alkaloids. A number of other less used drugs also were illegally labeled. Efficient government protection along these lines, especially during the war, is of benefit to the public, and is appreciated by the medical and pharmacal professions.

JERSEY VERSUS HOLSTEIN

The most striking differences between well selected dairy cattle with respect to their milk production are those attributable to the breed. It is literally true, of course, that beside breed and individuality, the period of lactation, the season of the year, feeding, care, and completeness of milking may affect the composition of the milk. Liberal feeding and exceptional care bring their reward in the form of an increased yield rather than a permanent change in the character or proportions of the ingredients of milk. We are not prepared to draw on ourselves the fire of the advocates—and they are in each case both enthusiastic and formidable — of the superiority of any of the well known breeds of dairy cattle by appearing as the champion of some rival breed. Both the Jerseys, at one extreme of the list, yielding milk containing nearly 15 per cent. of solids, including over 5 per cent. of fat, and the Holsteins, at the other extreme, with a more abundant supply of milk averaging only about 12 per cent. in solids and 3.5 per cent. in fat, have their champions for public favor. The average weight of a Jersey is from 800 to 900 pounds, and of a Holstein, 1,200 pounds. The comparison of large and small cows is thus involved. A person with judicial temperament and motives of strict economy might be inclined to estimate the cost of the important items relating to the milk production of each breed and thus form a judgment in the matter. Precisely this has recently been attempted at the Ohio Experiment Station[1] with results that seem, strange as it may appear on hasty consideration, to justify the propaganda of both breeds. In an exhaustive study of the economy of production of dairy cows from the feed consumed, it was found that the Holsteins, when the feed alone is considered, are able to produce milk more economically throughout the entire lactation period. The difference in economy of producing solids is not greatly in favor of either breed, although the Jerseys have a slight advantage. The Jerseys have a decided advantage, however, in the economy of producing fat. If the averages for each breed for the entire lactation period are used and the Jerseys are considered 100 per cent. efficient in producing milk, solids and fat from the digestible nutrients consumed, the Holsteins were 116.5 per cent. efficient in producing milk, 93.4 per cent. efficient in producing solids, and 74.5 per cent. efficient in producing fat. This indicates that the cows yielding high-testing milk produced solids and fats more economically than those producing low-testing milk, and also that the Jerseys gave in their product a larger return of digestible nutrients for each pound of digestible nutrients consumed than did the Holsteins. Where milk is sold by measure, that is, by the quart, regardless of quality differences, the volume is an important item. From this point of view it was found that the Jerseys consumed 163 pounds of dry matter and 106 pounds of digestible nutrients, and the Holsteins consumed 140 pounds of dry matter and 91 pounds of digestible nutrients for each hundred pounds of milk produced. It is not often that all parties to a controversy can find a morsel of satisfaction in the decision of the conflicting claims.

THE EFFECTS OF WAR ON MEDICAL RESEARCH

One of the significant effects of the war has been the turning of the attention of laboratory workers from some of the intricate, complex and wholly technical problems of research to those of immediate practical utilization and clinical bearing. These problems include efforts to secure new wound dressings; to discover serums or antitoxins to control the spread and the course of infections; to determine the causes and to discover means of prevention and treatment of those little understood conditions peculiar to the war, such as shell-shock, trench fever, trench foot, etc., and finally, to improve the methods of treatment of the common surgical conditions particularly associated with modern warfare. It is difficult to estimate today precisely the value of the procedures that have been adopted or the theories that have been advanced. The claims made for many of them, in some cases associated with an unfortunate sensational publicity, undoubtedly cause those easily swayed to form a too optimistic opinion. The meritorious virtue of some of the remedies has been lost in the clap-trap or mystery that surrounds them. Usually the value seems to reside in some already well known substances or procedures. While it is not to be regretted that enthusiasm and praise should be attached to the work of those engaged in actual warfare, overenthusiasm and false values should not be allowed to influence the opinions of scientists in an estimation of the procedures associated with the medicine and surgery of the war.

SKIN DIPHTHERIA

At Richmond, Va.,[1] during September, October, November and December, 1916, skin lesions that were at all suggestive of diphtheric infection were swabbed, and cultures were made. Also there was a wholesale swabbing of sores of all sorts. Out of 191 swabs examined, thirty-four were positive for diphtheria. This represents 17 per cent. of positive cultures, as compared with 23 per cent. positive during the preceding year. Pure cultures were isolated in eleven cases, all from schoolchildren, no two of whom were in the same family, although several attended the same school. Virulence tests in seven cases were positive. Each culture was grown on broth for about a week at 37 C. (98.6 F.) and then injected subcutaneously into the abdomens of two guinea-pigs, one of which received antitoxin. In no instance were there serious after-effects in the animal given antitoxin.

---

[1] Annual Report, Richmond, Va., Health Department, 1916, pp. 87, 94, 95.

For Prenatal Instruction.—The Department of Health of New York City has organized a special corps of nurses to instruct, advise and guide mothers during pregnancy in all matters pertaining to the health of themselves and their offspring and to aid in the reduction of the number of stillbirths. It is found that over 40 per cent. of the deaths of children under 1 year of age in New York City are due to congenital diseases; almost 37 per cent. occur during the first month, and three quarters of these during the first ten days. Eighty per cent. of all deaths occurring during the first months of life, and 90 per cent. of deaths during the first ten days of life, are due to congenital diseases, congenital deformities and malformations, inanition, marasmus, prematurity, accidents of labor, atelectasis, infection and hemorrhage of the cord, Winckel's disease, etc. The nurses arranged for are to be assigned to the infant welfare stations, and will be assisted in the prenatal work by the regular nurses of those stations. It is hoped that the physicians will avail themselves of the services of these nurses to the fullest extent.—*Weekly Bulletin*, New York City Department of Health.

Medical Mobilization and the War

TYPHOID VACCINE SUPPLIED BY ARMY MEDICAL SCHOOL

Between April 1 and November 1, the Army Medical School Laboratory, Washington, D. C., shipped 8,843,047 cubic centimeters of typhoid and paratyphoid vaccine for use by the Army and Navy. Enough typhoid vaccine was shipped to vaccinate 1,051,604 men; enough of the paratyphoid "A" and "B" vaccine to vaccinate 777,352 men. Since July 1, a triple vaccine, including typhoid and paratyphoid "A" and "B," has been manufactured and enough of this has been shipped to vaccinate 1,489,902 men.

DIRECTORS FOR MEDICAL SERVICE WITH AMERICAN EXPEDITIONARY FORCES

Major John M. T. Finney, M. R. C., U. S. Army, has been appointed director of general surgery with the American Expeditionary Forces in France; Major Hugh H. Young, M. R. C., director of venereal, skin and genito-urinary surgery, and Lieut.-Col. Joseph Siler, M. C., U. S. Army, director of the laboratory service.

Major John M. T. Finney, professor and head of the department of surgery in Johns Hopkins Medical College, went to France as head of the Johns Hopkins Hospital base hospital unit which was among the first to be ordered to active duty abroad. He was born in 1863 and graduated from Princeton in 1884, and from the Harvard Medical School in 1889.

Major Hugh H. Young, head of the department of urologic surgery and professor of urology at Johns Hopkins University, was ordered to active duty in France in June, 1917, to investigate the establishment of a urologic service. He was born in 1870, graduated from the University of Virginia in 1893, and received his medical degree from Virginia in 1894, and from Johns Hopkins University in 1895.

Lieut.-Col. Joseph Siler is especially noted for his research on tropical diseases and pellagra, particularly with the McFadden Pellagra Research Commission. He was born in 1875, and graduated from the University of Virginia in 1898.

DISEASE CONDITIONS AMONG TROOPS IN THE UNITED STATES

Extracts from Telegraphic Reports Received in the Office of the Surgeon-General for the Week Ending Nov. 9, 1917

1. Total Strength of Troops 1,042,225
   Admission rate per 1,000 (disease only) ....annual 1,236.5
   Non-effective rate (all causes) 31.1
2. National Guard—strength (camps) 369,148
   Admission rate per 1,000 all camps (disease only)..annual 1,517.3
   Non-effective rate all camps (all causes) 38.9

Camps showing admission rate for disease higher than average: Camps Bowie, Wheeler, Kearney, Sevier, Shelby and Cody.

Camps showing non-effective rate all causes higher than average: Camps Bowie, Wheeler, Sevier, Kearney, and Shelby.

3. National Army—strength (camps) 428,788
   Admission rate per 1,000 all camps (disease only) ..annual 1,139.9
   Non-effective rate all camps (all causes)................ 25.2

Camps showing admission rate for disease higher than average: Camps Pike, Jackson, Funston, Travis, Dodge, and Dix.

Camps showing non-effective rate all causes higher than average: Camps Pike, Funston, Jackson, Lewis, Dodge, Travis and Dix.

4. Venereal Disease—
   Admission rate Regulars 83.5
   Admission rate National Guard (camps) ....annual 151.5
   Admission rate National Army 115.3

Camps National Guard having rate above average: Camps Kearney, and Wheeler.

Camps National Army having rate above average: Camps Sherman, Travis, Dix and Jackson.

5. Number of cases of pneumonia 346
   Highest number in any one camp (Pike).................... 76
   Number of cases of meningitis 32
   Highest number in any one camp (Funston).................... 9

Medical Military Information.—A list of pamphlets of interest to medical officers of the Army will be found on advertising page 28 of this issue.

THE CAMP GREENLEAF SCHOOL OF MILITARY HYGIENE

Within the past year we have become interested in the efforts of the State Board of Medical Examiners of Pennsylvania to arouse interest in universal training in hygiene as a requirement for candidates seeking license to practice medicine.

The Pennsylvania board made this a practical fact by securing a state law which prohibits the licensing of a physician to practice medicine in that state unless the applicant has had a practical camp course in military hygiene. The bill provides, however, that this requirement is waived if the government of the United States fails to provide the necessary course.

When this camp opened, June 1, 1917, one of the ambitions of its commandant was to found a school of military hygiene on such a firm basis that it would last, not only for the period of the war, but for all time. A tiresome recital of disappointing setbacks and tribulations would profit little, and the announcement that the school is now in full operation, built on a foundation of permanent proportions, is the fact that we wish to set forth. The school has already begun to accumulate valuable property, such as microscopes, selected microscopic specimens, models of apparatus, books and pamphlets. In addition to this, arrangements have been completed to publish in full the valuable lectures delivered in the class rooms.

These lectures are in large part delivered by members of the student body, many of whom are specialists in some particular branch of sanitation. The school is a school plus a clearing house of knowledge. It is amazing to find how much talent drifts into these camps, and it is believed that the accumulated work of the attendants and instructors, published in book form, will make a valuable contribution to the literature of the country.

At the close of the camp, the literature and property, scheme of operation, and all other matter connected with the school, including models of sanitary apparatus, will be presented to the world's greatest sanitarian, the Surgeon-General of the Army, with the expressed hope that it may be found practical to make it a permanent benefit to the country.

A description of the school, written by the director, follows:

The Camp Greenleaf School of Military Hygiene has for its object the intensive training of Army surgeons in the field of camp sanitation.

The basic curriculum of the school comprises didactic and practical instruction on such fundamental subjects as camp sites, draining; approved methods for the disposal of kitchen, human and animal waste; the necessity for the sanitary policing of barracks and surroundings; water supply, quality, quantity and approved methods of purification; the inspection of the mess, and mess kitchen, including the food, its mode of preparation, the means for preservation, general cleanliness, and prevention of waste; insects as nuisances, sleep disturbers and transmitters of disease; the cycle of development of the common insects, and the approved methods used for the suppression of insects; the transmissible diseases and the approved methods for their control, including isolation, disinfection and prophylactic vaccination; the diseases of camp life in the several seasons, and military administrations. The sanitary clinics are an essential feature of the instruction. These complement the didactic teaching. They are entirely practical field work. Convenient groups of student officers are assigned for duty on problems involving drainage, road construction, insect abatement, conduct of picket lines, construction and care of latrines, disposal of waste, mess kitchen inspection, construction and care of the various types of incinerators and grease traps, water purification and storage, administrative work, etc. Their work is under the critical supervision of the staff of instructors.

In addition to the foregoing routine instruction, lectures are given on cognate subjects by the staff and student members of the school. Such lectures are given in the barracks occupied by the school and only to the class in hygiene. The character of the lectures by the student officers varies with the men available in the school at the time. To illustrate: Since the school was organized, lectures have been delivered by members of the class on the following, among other subjects: pellagra; malarial fever; vaccine therapy; fleas and disease; rat proofing of buildings; customs of the service; paper work in the Army; rural sanitation; hookworm; running a mess; duties of a quarantine officer; ship disinfection; military map making (with practical work in the field); amebic dysentery; refuse disposal; typhus in Serbia; the Kentucky closet; routine work in Panama; operation of sewage disposal plants; yellow fever; first aid in sanitation; causative factors in epidemics; special quarantine measures; building disinfection (a demonstration); hygiene of ventilation; water purification; sanitation in building construction; details of sanitary inspection; military map reading.

The instruction in the school of hygiene is given in hours that do not conflict with the general instruction given to the entire student officer body, and members of the school are required to attend such instruction as well as the special instruction given in the school. While in the school of hygiene, the student is relieved from military drill, but no student officer is assigned to the school who has not had at least two weeks of such drill, and the plan, therefore, does not materially interfere with the training arranged for student officers. As with other instructional departments of the camp, quizzes are held regularly by officially appointed instructors, and the students are graded according to the progress made in the work. Weekly records of such grades are made.

Class work, Medical Officers' Training Camp, Fort Riley, Kan.

The staff of instructors comprises Major Alexander C. Abbott, M. R. C., director, and Capts. William K. Evans, M. R. C., and M. L. Todd, M. R. C., assistant directors.

There are fifty students. The course of instruction covers four weeks from the date of assignment, unless it is obvious at the end of the first week that the student, for various reasons, is not adapted to sanitary work. In that event he is transferred to the company from which he was assigned, and another is detailed in his place. In the immediate future, the number of students of the company will be increased to 100, with a corresponding increase in the staff of instructors. As a saving of time, only students of Grade B and up will be assigned to the company.

Throughout, the instruction is as practical as possible, the student officers' camp, the outlying organizations, and the surrounding camps serving as excellent object lessons.

Henry Page, Colonel, U. S. Army.
Commandant, Camp Greenleaf, Fort Oglethorpe, Ga.
Alexander C. Abbott, Major, M. R. C.
Director, Camp Greenleaf School of Military Hygiene;
Director, University of Pennsylvania Laboratory of Hygiene.

NEWS OF THE CANTONMENTS

Twenty-Eighth Division, Camp Hancock, Augusta, Ga.

During the past week, Captain Roux, specialist in orthopedics, has been visiting our camp and lecturing on military feet and shoes. Proper exercises in bending the ankles outward and rising on the toes were described for weak feet; dressings and modifications in shoes were described also.

The entire division is being trained in the use of the gas mask, under the direction of Captain Stone and Lieutenant Russell. Cardiac, tubercular and nerve specialists are sifting out men with defects.

The course of instruction for medical officers is comprehensive and will require considerable time for completion. We hope to complete courses in litter bearing, first aid, pack mule drills, etc., on field day. It is also planned to have an original medical article competition for medical officers.

Thirty-Fifth Division, Camp Doniphan, Fort Sill, Okla.

The arrival of 3,000 drafted men by way of Camp Funston, among whom were several men with measles, has unfortunately increased the morbidity statistics for Camp Doniphan. Two cases of cerebrospinal meningitis also promptly developed among the new arrivals, and twelve carriers were found among contacts. All were immediately placed under rigid quarantine, and it is hoped that the situation will be controlled.

The care of the sick unfortunately is still handicaped by the fact that the new base hospital, with the exception of a few wards, is not yet ready for occupancy. Construction work, however, is being pushed with all energy, and it is hoped that within two weeks a considerable number of the wards of the new institution will be ready.

LYCEUM WORK

Lyceum work under the able direction of Lieut.-Col. W. T. Davidson is progressing satisfactorily and is widely appreciated. Meetings are held Monday, Wednesday and Friday evenings. The Monday meeting was devoted to the reports of the special examining boards. Capt. Ralph Brown, for cardiovascular diseases, reported on the examination of 15,000 men since September 15, with forty rejections. Capt. Brown briefly classified the classes that come up for observation under the headings, first, myocardial; second, valvular; third, functional. The first group is practically eliminated in the type of men that come up for examination; most cases fall within the last two groups.

Lieutenant Little of the tuberculosis board reported that his board had rejected 0.03 per cent. out of 15,000 men examined since the board began its work here in September. The number of these rejections, he said, is likely to increase as the facilities for examination improve. At present the work has to be done under considerable difficulty, and does not permit of the refined diagnoses possible under the best circumstances.

Lieut. Thomas Heldt of the psychiatric board reported on the work of his board. Since September 4, 15,000 cases were examined, with 1 per cent. of rejections. The type of cases were found in the following order of frequency: mental deficiency, constitutional psychopathic state, psychoneuroses, nervous disease and injuries (including the epilepsies), inebriety (alcoholism and drug addiction), and psychoses.

Wednesday's meeting was devoted to short talks by the chiefs of staff of the base hospital. Major P. B. Connelly, in charge of the base hospital, briefly explained the organization and present facilities of the hospital, and assured the men of the field of his heartiest cooperation through the personnel of his command.

Major J. Barksdale, chief of the surgical staff, called special attention to the need for careful examination of men complaining of "pain in the belly." Too often these cases prove to be appendicitis, which is brought to operation under a serious handicap. He cautioned against the administration of purgatives in cases of suspected appendicitis. The records of the surgical department give a splendid showing with 389 operative cases since September, 150 of which represent major work, with but one death.

Major Sidney Strauss of the department of internal medicine discussed briefly the symptomatology and diagnosis of the diseases encountered at this camp thus far. He urged that all patients with a temperature of more than 100 F. should be transferred to the hospital.

Major Magruder of the eye, ear, nose and throat department called attention to the relatively large number of disease carriers (diphtheria and Vincent's angina) that were found among those referred to his clinic. He advised that men with chronic middle-ear infection should be recommended for discharge, since surgical interference cannot improve them for service in the Army.

Major G. C. Ruhland, in charge of the laboratories, spoke briefly on methods of securing and transmitting specimens for laboratory diagnosis.

Lieutenant Hoffmeier, roentgen specialist, and Lieutenant Woods, dermatologist, also spoke briefly on matters relating to their specialties.

Friday's meeting was given over to a paper on camp sanitation by Major Phillips, chief sanitarian of the division surgeon's staff. Major Phillips admirably covered the essentials of camp sanitation and hygiene; his paper was received with a great deal of interest and was profitably discussed.

The discovery of a second case of anthrax, also occurring on the patient's face, suggests the possibility of anthrax infection from shaving brushes, and special attention is being directed toward this possible source of infection.

PERSONAL

Colonel Lewis of the Regular Army and Major N. M. Black, M. R. C., have arrived in camp on an inspection tour of National Guard and Army camps.

Lieut.-Col. Robert Carswell of the Regular Army has arrived and has taken charge of the administration of the post hospital.

Thirty-Ninth Division, Camp Beauregard, Alexandria, La.

Many changes in the Medical Department of the camp have taken place. Many more troops have arrived; there are now more than 20,000 here, and the number of medical officers has increased to over 100. Owing to the fact that 9,000 draft men have been sent here from Camp Pike, who brought with them from that place the remains of a rather extensive epidemic of measles of a mild form, and furthermore owing to the fact that these men are distributed throughout the various organizations of the camp, a rather rigid quarantine is in force. Two field hospitals are now in operation, one taking care of the measles and the other one handling the mumps of the camp. This relieves the base hospital of congestion and allows it to take care of the more seriously ill.

Col. Henry C. Fisher, M. C., inspector from the Surgeon-General's Office, spent two days here making a general inspection of the entire medical department, including the sanitary conditions.

On November 12, Captain Gephart of the Surgeon-General's Office visited the camp on a tour of inspection in the interests of food conservation.

Captain McMillan of the Surgeon-General's Office made a tour of inspection on November 15, in the interests of the venereal work of the camp.

The entire body of medical officers of the camp was invited to attend a meeting of the Rapides Parish Medical Society on November 6. (It will be noted that the term "parish" is employed in Louisiana instead of "county.") The meeting was held in the city hall, and about fifty medical officers and about fifteen local civilian physicians were present. Mayor Whittington of Alexandria told the officers that the city administration would give them every possible aid in sanitary matters, and was roundly applauded. P. A. Surg. H. S. Smith of the United States Public Health Service, who is in charge of the sanitation of the extra-camp area, gave a very interesting talk on the work he and his assistants are doing. Contract Surgeon Wright of Monroe, Ia., who has been on the tuberculosis board, told of his experiences with the intravenous administration of quinin in malaria. Short talks were also made by Colonels Smart and Schauffler, and Majors Lull, Burrus and others. After the meeting the guests and their hosts adjourned to the banquet hall of the Hotel Bentley where a delightful supper was served which was thoroughly enjoyed by all.

BASE HOSPITAL NOTES

The base hospital has been running in full swing for some weeks and there are now about 400 patients quartered there.

The laboratory is exceedingly well equipped and excellent work is being done. One deficiency is that it is not equipped to perform the Wassermann test. Specimens of blood and spinal fluid for this test are sent to the department laboratory in Atlanta, Ga., and from five to seven days elapse before a report is returned. This causes a great deal of inconvenience, and it is hoped that before long the base hospital will be equipped and authorized to perform this test.

Only two cases of epidemic cerebrospinal meningitis have developed in camp. Both are being treated in the base hospital.

The operating pavilion was opened recently and already several operations, both major and minor, have been performed.

The venereal section occupies two wards and has been practically full for some time. Only the acute cases are kept for treatment, all chronic cases being returned to their commands for treatment in the regimental infirmaries. A large percentage of the patients contracted the diseases before coming to camp, and it is thought that as soon as all of the troops have arrived and have settled down to the routine of intensive training the venereal rate will drop materially.

Lieut. Adrian Landry, who was home on a month's sick leave, recently returned greatly improved in health. He has been assigned to the laboratory.

Seventy-Seventh Division, Camp Upton, Yaphank, N. Y.

Undoubtedly the most important medical event that has taken place in Camp Upton during the past month has been the removal of the base hospital from its temporary barracks to the new hospital unit. This group of some seventy buildings is located about two miles from the camp proper, so that the transportation of patients from the camp to hospital and back affords considerable valuable practice for the ambulance companies, which undertake the major part of this work.

The hospital is not finished, and but twelve wards are completed and occupied. The quarters for the enlisted men are practically completed, and though not yet supplied with steam heat, they are reasonably warmed by stoves. The men are supplied with assembly rooms, a point that thus far has been utterly neglected in the officers' quarters, which are not yet ready for full occupancy. Most of the officers, for the time being, are lodged in the receiving pavilion. It is much to be regretted that no provision has been made in the hospital for an assembly room for officers in which a library and rest facilities are provided, but we are informed that this matter is to be considered favorably later, and that ample provision has been made for standard medical books and journals.

The pleasure of moving into the new unit has been greatly dampened by the edict, which applies alike to patients, enlisted men and officers, that there is to be no smoking in or about the hospital unit. That such a ruling is absolutely necessary in buildings of this type, and particularly in the unfinished state with much inflammable material lying about, is obvious; but the lamentations of Moab for her children was joyous beside the wail that has gone up from the base hospital, and during off moments the surrounding roads are crowded with disconsolate men and officers seeking solace in the weather outside plus nicotin, rather than relative comforts inside minus tobacco. It would seem too much to expect that optimism should reign within the walls of the hospital at such a time of famine, but none the less the spirit that seems to imbue the men of the staff is anything but depressed.

The messing facilities in the unit are as yet incompletely developed, but are quite adequate for the immediate needs of the service. Luxuries, in the way of crackers, cookies, jellies and preserves, are being contributed in great generosity by the women of New York and particularly by those of the adjoining towns. It is notable, as compared with former occasions, that contributions of this nature are almost without exception sensible and well adapted.

INSTRUCTION OF HOSPITAL STAFF

Courses of instruction of the base hospital staff are being conducted, mostly by the members of the staff under the immediate direction of Major Jay D. Whitham, while that of the medical organizations within the camp proper are under the control of Lieut.-Col. Reynolds. These courses cover military-medical subjects, and paper work—which is so very needful in all military establishments—in addition to the usual professional work and subjects. After the hour of evening instruction, a short session of clinics is conducted, cases of particular interest being brought in, demonstrated, and discussed by the members of the various services.

DISEASE INCIDENCE

Comparison with the sick percentage of the other National Army cantonments shows that Upton is particularly fortunate in nearly all particulars. Our relatively low rate of venereal infections has excited considerable comment, and those cases of this class reporting at the regimental infirmaries and at the base hospital, with few exceptions, are instances contracted before entering the military service. Stations for venereal prophylaxis under the command of the medical staff of Upton, and attended by the men of the hospital detachment, have been established in New York and Brooklyn. Similar measures are contemplated for certain of the villages nearer the encampment. Through these, and the full instruction of the men of the command, it is hoped to obviate any serious problem in this respect.

EXAMINATION OF RECRUITS

Much of the time of the medical staff of the main camp is still occupied in the examination of recruits. A careful tabulation of this work is being kept by Lieutenant Freeman, which affords some very interesting data. Forty-two medical men working at one time have been able to examine on an average of 267 men per hour, including the special examinations, which frequently consume much time. The staff of examiners is working in three shifts of from four to five hours each. They are assisted by a total number of 180 enlisted men. The total staff of examiners consists of eighty-four regular examiners and nine specialists.

Defects in vision have been by far the most frequent cause for rejection at Upton; chronic purulent otitis media has been the second most frequent factor, hernia the third, organic heart disease the fourth, and defective and deficient teeth the fifth.

DISTINGUISHED GUESTS

Distinguished medical visitors to the camp have been Colonel Shaw, inspector of base hospitals; Colonel Reynolds of the Surgeon-General's Office, best known to us as brother of "our" Colonel Reynolds; Dr. Davenport, the distinguished biologist, who has assisted us regularly in certain of our examinations, and Major E. K. Dunham, whose researches on water purification, and in association with Dakin of the chlorin methods of disinfection, are promising such flattering results. Several days ago Major Flexner of the Rockefeller Institute paid the camp a brief visit. Major Webb, commandant of the Bellevue Hospital Unit, and Major Leon T. Le Wald, instructor in roentgenology, both retired officers of the regular service who have generously reentered at this time of crisis, are guests at the base hospital. Dr. Glentworth Butler and Dr. Tasker Howard of Brooklyn have been working as cardiovascular experts with us, and their return home is much regretted by us all, in both personal and professional respects.

Eighty-Fifth Division, Camp Custer, Battle Creek, Mich.

Special instruction and preparations are being formulated by the division surgeon for the rapid and complete examination of the increment of the draft that is expected this week. It is expected that the entire work of examination will be completed in two weeks. Special arrangements have been made by the division surgeon so that all medical officers will be given an opportunity to become familiar with the paper work necessary in handling these examinations.

During the last week courses for instruction for all medical officers have been progressing rapidly. Captain Donnelly and Lieutenant Drowne have been giving talks on the medical paper work and that pertaining to the Quartermaster Department, respectively. Majors Bremerman and Jackson, directors of field hospitals and ambulance companies, gave practical talks relative to their special work.

Major Wood, commanding officer of the base hospital, has arranged for special instructions three evenings a week. This consists in the work of medical organizations in actual combat, in reports on military surgery as found in the various medical journals and in clinics held by the officers of the base hospital on cases of military interest. The evening classes have proved of exceptional merit and are attended practically by every medical officer in camp.

NOTES

Capt. Constantine MacGuire, commanding officer of the Three Hundred and Thirty-Seventh Ambulance, was relieved from duty at Camp Custer and ordered to report at Camp Mills.

Major J. F. Edwards has reported as chief sanitary inspector to fill the vacancy left by Lieut.-Col. W. A. Powell, who was ordered to Camp Devens.

Major Lewis Wine Bremerman, director of field hospitals, addressed the Kalamazoo Academy of Medicine, November 13, on the subject, "What the Medical Profession Owes the Country." There were about thirty-five members present. The meeting was preceded by a luncheon in honor of Major Bremerman.

A board of experts on tuberculosis has arrived in camp and their work of examining all men in the camp is progressing rapidly.

Lieutenant Tyner of Field Hospital No. 339 is absent in the East on a five-day leave of absence. It is understood that he may have a bride with him on his return.

Lieutenant Morris of Field Hospital No. 338 is on leave, visiting in Detroit.

The rate of venereal disease is decreasing remarkably in this camp. Last report showed 1.85 per cent. covering all forms of disease of this character. These facts speak well for the moral standing of the division.

Eightieth Division, Camp Lee, Petersburg, Va.

BASE HOSPITAL NOTES

The hospital is nearly completed, and the operating rooms are in such a state of completion that they are used daily for all kinds of operative cases. The successful opening of the operating room is due, in a great measure, to the untiring energy of the operating room nurse, Miss Byrnes, whose originality and adaptability have hastened its opening.

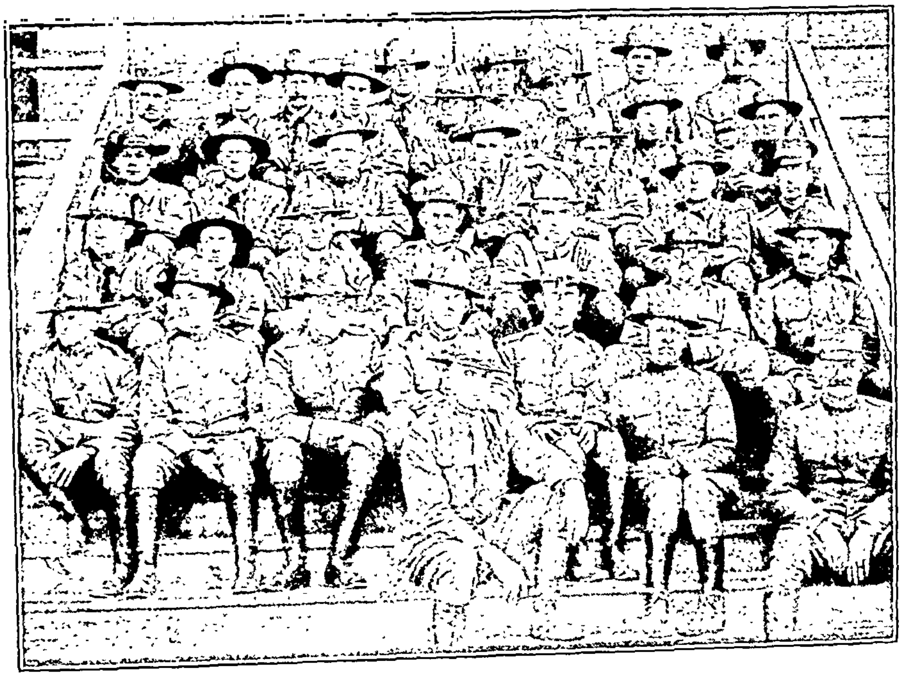
The force of nurses who are to care for the hospital patients is augmented from day to day by new arrivals; thus far they number twenty-six. About seventy-five are expected when all have reported.

There are some queer bed fellows in the receiving ward barracks, now temporarily occupied by the base hospital surgeons. Lieut. J. J. Beaton, M. R. C., made a hurried and undignified exit from his bed at 1 a. m., bringing with him all the bedclothes and a 6-inch slider terrapin (*Pseudemys rubriventris*) that some thoughtful friend had deposited in his bed earlier in the evening. The evening recital of yarns by the noted liars is still kept up. Gulliver and Baron Munchausen would blush with envy and chagrin could they be present. Hampton M.D.'s will recognize the chief Ananias.

The roentgen-ray outfit has been set up by Captain Merritt, M. R. C., and Lieut. Victor Noel, S. C., and some excellent pictures have already been taken. The laboratory is doing great work and materially aiding the whole staff by prompt and rapid reports. Men exposed to meningitis are now being examined for carriers. The new quarters for the hospital staff are ready for occupancy and the officers are moving in. Major Hope reports that on a recent visit to the Chesapeake region he found the oysters in prime condition and of excellent flavor, and that he ate a barrel on the half shell to be sure that they were.

The base hospital staff has been delighted and very much improved in every way by the presence of Mrs. Ferdinand Schmitter, the wife of the commanding officer, and her sister, Miss Bradstetter, who have added the charm of social life to the camp.

The first of the regular weekly clinical meetings was held at the base hospital, Thursday evening, November 8, and was attended by all the medical officers of the base hospital and the division. Major Ferdinand Schmitter, M. C., presided. The meeting was under the direction of the chief of the medical service, Major Lawrence Litchfield, M. R. C.



Officers of base hospital, Camp Lee, Va. From left to right: lower half row, Major Ferdinand Schmitter, M. C., U. S. Army; Major E. W. Day, M. R. C.; Major Joseph W. Hope, M. R. C.; lower full row, Major William E. Peple, M. R. C.; Major Samuel B. Moore, M. R. C.; Major Lawrence Litchfield, M. R. C.; Major J. B. Clark, M. R. C.; Capt. Beverly R. Kennon, M. R. C.; Capt. L. E. Hetrick, M. R. C.; second row, Capt. Lauren Thomas, M. R. C.; Capt. Henry B. Gillen, M. R. C.; Capt. Edward M. Parker, M. R. C.; Capt. Henry R. Weston, M. R. C.; Capt. Hugh Beebe, M. R. C.; Lieut. P. C. Riley, M. R. C.; Lieut. J. J. Beaton, M. R. C.; third row, Lieut. Nathaniel Barnard, D. R. C.; Lieut. Clay M. Easter, M. R. C.; Capt. Edwin A. Merritt; Lieut. I. H. Goldman, M. R. C.; Lieut. F. B. Humphreys, M. R. C.; Lieut. Samuel E. Lambert, M. R. C.; Lieut. Clarence S. Yoakum, S. C.; top row, Capt. W. S. Hunter, M. R. C.; Lieut. Edward S. Jones, S. C.; Lieut. Thomas S. Lee, M. R. C.; Lieut. T. F. Smith, D. C.; Lieut. F. J. Smith, M. R. C.; Lieut. H. A. Rothrock, M. R. C.; Lieut. C. H. Perry, S. C.; Lieut. W. S. Hunter; Lieut. R. L. Davis, M. R. C.; Lieut. George R. Moffitt, M. R. C.

Contract Surgeon Thomas S. Lee presented a case of dexiocardia, the only case detected in the examination of 40,000 recruits. Major Schmitter stated that in the examination of 40,000 recruits at Fort Slocum, one case of dexiocardia was diagnosed.

Lieutenant Phails then showed a case of lichen planus, and one of pityriasis rosea. The discussion of the latter case elicited the fact that a positive Wassermann test had been obtained in a number of cases of pityriasis rosea. Two interesting abnormal gaits were demonstrated by Major Litchfield; one was possibly sacro-iliac disease; the other patient had an unusual rolling gait, walking on the outer side of the feet, no change in sensation or reflexes, and no abnormality in the joints. This case was believed to be one of hysteria.

Lieut. P. C. Riley, M. R. C., of the medical staff, told of the number of cases of communicable disease treated in the base hospital since it was opened: thirteen cases of lobar pneumonia, with no deaths; four of typhoid fever (infection prior to arrival), with one death; seven of meningitis, with one death; one of scarlet fever; two of chickenpox; twenty-two of mumps, and twenty-six of measles.

The subject of the evening was cerebrospinal meningitis, the clinical features of which were discussed by Major Litchfield. Lieut. E. J. Asnis, M. R. C., then discussed the subject of meningitis carriers and method of detection. Lieut. F. B. Humphreys demonstrated the brain of the patient with meningitis that had died, and made some interesting remarks on the different immunologic reactions of the different types of meningococci.

Eighty-First Division, Camp Jackson, Columbia, S. C.

We have moved to the base hospital. A more beautiful and healthier site could hardly be found. To stand on the misty hilltop to welcome the glorious sun and fill the lungs with pure air makes a man thankful that he is an American, beginning his real duty to the world.

ORTHOPEDIC WORK

Among the specialists who are visiting Camp Jackson is Capt. J. T. Rugh, M. R. C., Philadelphia. Prophylaxis along orthopedic lines is being organized in Camp Jackson; lectures pertinent to the care of the feet, joints and spine are given to the medical and line officers of every brigade and of independent organizations. The instructions deal purely with the soldier; every effort is directed toward rendering him more efficient by personal attention to the fit of the shoes, proper manner of walking, and strengthening of his foot and leg muscles by graduated exercise, and greater emphasis is placed on the importance of this care during the first six or eight weeks of his training. The care of the shoes, stockings and feet is also taught to the officers and by them to their men, and everything that will contribute to greater efficiency is being utilized in all channels.

Captain Rugh is supervising orthopedic surgeon in charge of five camps in North Carolina, South Carolina and Georgia, and his work and efforts are meeting with the heartiest cooperation among the officers in all organizations. A daily orthopedic dispensary under the care of Lieutenant Garrenton has been established. Foot inspection of all in the camp will be made, and potential disabilities will be recognized early and prevented by proper means.

TUBERCULOSIS AND CARDIAC SERVICE

The Medical Department of the government is doing a great service for the people of America. A board for the special examination of all members of the command for pulmonary and cardiac defects began work in camp this week. It consists of Major Boyce, M. R. C., Pittsburgh, president; Lieuts. Leopold Shumaker, Edgar W. Cowan, Owen S. Deathridge, Ephraim Goldman, Urban H. Reidt and Edward N. Packard, and Surgs. Howard Van Rensselaer, John R. Williams and Hugh F. Keating. Recently Major Boyce addressed the meeting of the base hospital lyceum on the pathology and diagnosis of tuberculosis, laying especial stress on the value of close coordination between clinician and roentgenologist. Major Herrick, chief of the medical service, will have the cooperation of this board in this service.

PERSONAL

The new commander, Major Thomas J. Leary, who recently returned from Panama, where he was chief surgeon in command of the Colon Hospital, has taken firm hold on the base hospital, and things are moving with a swing. Visiting him are his wife and child from Philadelphia. Mrs. Leary, being the wife of a Regular Army man, has been his companion in Panama and the Philippines.

The wife and the daughter of Captain Baeslack, chief of the pathologic laboratory, are visiting in Columbia. Captain Baeslack has done original work on cancer, sarcoma, syphilis and other diseases.

Dr. F. Victor Laurent, formerly baritone of the Paris Opera, Covent Garden and Metropolitan companies, joined the Medical Reserve Corps last April as first lieutenant, and after a course of training at the medical officers' training camp at Fort Oglethorpe was sent to this camp to make examinations in his speciality, otolaryngology. Lieutenant Laurent is now stationed at the base hospital, and in addition to his medical and military duties is teaching his fellow officers French conversation, and finds time to sing occasionally in some of the churches in Columbia. Several weeks ago he sang "It is Enough," from "Elijah," at Trinity, and repeated this the following Sunday at the First Baptist Church by request of Lieutenant-Governor Bethea, who is a warm admirer of the Mendelssohn oratorio. The doctor had arranged for some joint recitals with Yvonne de Treville, the distinguished coloratura soprano, for this season; but after accepting his commission, these engagements were canceled. It is possible, however, that they will give a joint recital at the camp during the winter.

Lieutenant Laurent lived for five years in Paris, and is anxious to get to the front where many of his old comrades now are.

Major J. Stone, chief of the surgical service, received his commission in October.

Captain Pendleton of Portsmouth, Va., has just received his commission as captain.

Mrs. Burton Chance, wife of Captain Chance, and son recently visited Columbia and Camp Jackson.

Lieut. Harry Judge of Albany, N. Y., has been assigned to the ophthalmologic department.

Major Greenwood has visited Camp Jackson and other cantonments in the interest of eye departments.

Eighty-Fourth Division, Camp Zachary Taylor, Louisville, Ky.

FOOD WASTE

Numerous letters have been received by the daily press in Louisville, attributed to German propagandists, in which it is charged that food by the wholesale is being wasted at Camp Zachary Taylor. Some of the letters have been turned over to the intelligence section of the general staff of the Eighty-Fourth Division for investigation. It is a fact that the garbage contractor who expected to get 60,000 pounds of garbage daily from the entire camp is receiving only 8,000 pounds, which of itself shows that waste is at a minimum. The problem of saving food, until recently, has fallen on Major Luther Poust, chief sanitary inspector, who has under his direction six lieutenants of the Medical Reserve Corps who make the rounds of the camp every morning and see that all sanitary rules are obeyed, and that nothing is found in the garbage cans other than what should be there. In addition, a commissioned officer must be in attendance when mess is served, to prevent waste.

Here are a few of the instructions that every mess sergeant and cook must follow in his kitchen: The portion of bread bitten by a soldier must be cut off, placed in the oven and sterilized, and saved for bread pudding and meat dressings; oatmeal and corn grits must be saved for puddings and dressings; bones, after the meat is removed, are saved and boiled for soup; all left over meats and fats are boiled and rendered, and used for frying and flavoring.

A soldier is expected to eat as long as he is hungry, just so that he does not waste.

A commissioned officer is on duty at the garbage incinerator, and closely observes every can that comes there. The inspection of garbage does not at first thought seem to be a very important duty for a medical officer to perform; yet this is one of the most important functions of the Sanitary Corps. Lieut. Lee Ernstberger of Louisville is one of this corps detailed for the inspection of garbage, and reports that there is no waste at the camp.

Orders were issued, November 6, designating Col. J. H. Allen as food conservation officer of the cantonment. Under the orders, all regimental, battalion and independent unit commanders must submit every ten days, commencing November 10, a report to the food conservation officer showing the amount of fresh and canned beef, fresh pork, bacon, bread, sugar and lard used by their respective commands, and this report must embody also the respective strength of the commands. Mess officers will be required to keep a daily report showing the number of meals prepared for officers and those actually served, together with the amount used of the foregoing foodstuffs. The order enjoins every enlisted man to do all in his individual power to prevent waste of food. One of the regulations of the sanitary corps is that garbage cans be kept within the screened kitchens, in this way flies being reduced to a minimum. Garbage cans are chemically treated and steamed, eliminating entirely the sour smell ordinarily present in these cans.

MEASLES

The entire Three Hundred and Thirty-Sixth Infantry, composed almost entirely of Kentucky soldiers, has been quarantined on account of an epidemic of measles. Eighty-one cases have been reported from this regiment. They came in so fast as to swamp the base hospital, and a company barracks in the regimental confines was requisitioned for a temporary hospital. The quarantine order applies to officers and men alike, not a man being allowed to leave the regimental area. The epidemic began three weeks ago and was traced to a drafted man in whose home there was a case of measles when he left for the camp. Practically every company has had men affected. The disease generally has been in a mild form. One death has resulted from a complicating bronchopneumonia. Practically none of the men from Louisville have had it. The quarantine order prevented a number of Louisville men obtaining leave in order to vote.

On the first evening of the session of the Kentucky State Medical Association, the members heard a stirring patriotic address by Governor A. O. Stanley, given especially before the medical members of the draft examining boards of the state. At the conclusion of his address, three members of the reviewing board at Camp Zachary Taylor were called on to explain in brief in regard to the chief causes for final recommendation for rejection by the reviewing board. Major Walter Hamburger, president of the board, called attention to the fact that approximately but 5 per cent. of all troops received were rejected, a smaller percentage in comparison with nearly all of the other camps. The division surgeon had stated that probably many men were accepted, with perhaps no visible or demonstrable lesion, who were in such a general physical condition, perhaps of malnutrition, that they would finally not make good soldiers.

Major Hamburger mentioned, as among the most frequent causes for rejection, hernias, flatfoot, trachoma, congenital amblyopia, tuberculosis, asthma, chronic valvular disease of the heart, and active syphilis.

Lieut. Willard J. Stone, in charge of the cardiovascular examinations, reported that of 201 heart patients, 43 per cent. had been rejected. Of this number, mitral regurgitation caused 54 per cent.; mitral stenosis with regurgitation, 16 per cent.; simple tachycardia, 10 per cent.; hypertension, 7 per cent., and hyperthyroidism, 5.7 per cent. A large number of men with accidental or functional murmurs were referred to the board by the regimental surgeons, and 35 per cent. of these were accepted. He mentioned the effort test that was used in these heart examinations, the pulse rate and blood pressure being taken with the patient recumbent; then with the pressure cuff in position, the soldier is caused to take 100 short hops on alternate feet, the blood pressure being then taken within fifteen seconds after the effort. The ratio of rate and blood pressure before and after effort is carefully recorded and compared. If the rate increases inordinately while the blood pressure does not, the candidate is not fit to serve.

DIVISION SURGEON'S REPORT

The report of the division surgeon, November 11, shows a total of 550 patients in the base hospital, and 420 under treatment in the regimental infirmaries. The venereal cases show 455 cases of gonorrhea. Venereal prophylaxis was given 126 times. Twenty per cent. of all sickness in the command is venereal. In the base hospital are nineteen cases of pneumonia, with no new cases; three cases of parotitis; four of meningitis; four meningitis carriers, and 186 cases of measles. November 10, 3.27 per cent. of the command were ill. The lowest rate was 1.67 per cent.

The first meningitis carrier slept next to the first man who developed meningitis, and has remained well, as have the other three carriers. These men have been treated by the dichloramin-T solution and are now free of organisms.

The reviewing board up to November 11 had rejected 1,689 men.

Diphtheria developed in the Three Hundred and Thirty-Third Infantry, and cultures were taken from the throats of all the rest of the men and were found negative. In the future the Schick test will be used, as the diphtheria toxin is now on hand for that purpose.

The entire Three Hundred and Thirty-Sixth Regiment of Infantry is quarantined for measles, and one battalion of four companies in the One Hundred and Fifty-Ninth Depot Brigade.

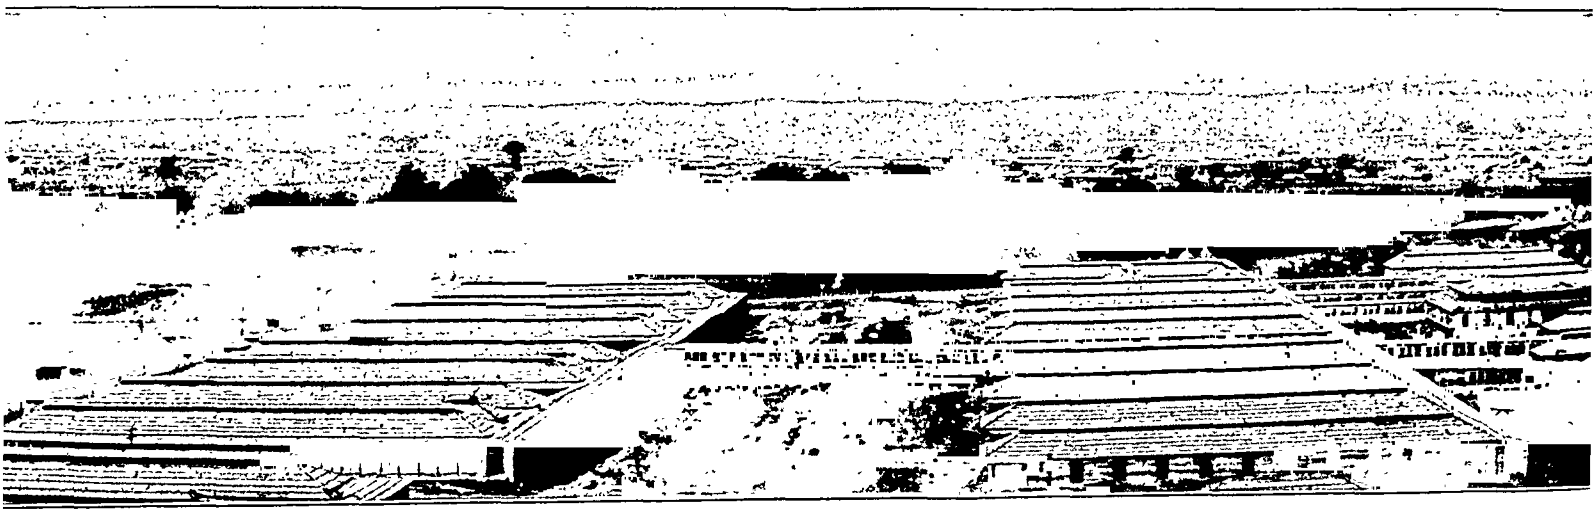
Capt. Herbert Fox and Mrs. Fox have been called to Philadelphia by telegram announcing a serious injury to their son caused by an automobile.

Eighty-Sixth Division, Camp Grant, Rockford, Ill.

Specialists have been assigned to the camp for consultation on doubtful cases so that in every questionable case the patient may have the benefit of an expert's opinion. Tuberculosis is especially looked for and the following method has been effective in finding mild and incipient cases:

An enlisted man makes out the roster of the company, using a separate slip for each man. This slip has the man's name, rank and organization, pulse and temperature, and the heart and lung findings. Half an hour before the appointed time, four enlisted men go to the barracks and take the pulse and temperatures, which they record on the slip. The examining board goes to the barracks and examines the men. Each man strips to his waist and stands by his cot with his slip. This method creates very little confusion and inconvenience. Positive or doubtful cases are referred to the tuberculosis expert who is attached to the base hospital. It takes about five minutes to examine a man's chest, and each examiner can examine about seventy-five a day. When heart cases are found, the patients are referred to the cardiovascular expert, who is also attached to the base hospital.

The Base Hospital Medical Society is organized, and holds weekly meetings at which papers on various subjects are read.



Base hospital, Can

No communicable diseases have been encountered among the 4,500 horses and mules received at the remount station, and from there distributed to the various regiments.

PERSONAL

The president-elect of the Kentucky State Medical Association, Dr. Phil Stewart of Paducah, the retiring president, Dr. Milton Board of Louisville, and the secretary, Dr. Arthur T. McCormack, are members of the Medical Reserve Corps, in active service. The orator in surgery, Dr. Fred L. Koontz of Louisville, was unable to be present on account of a special detail to a point of instruction.

First Lieuts. Lauren N. Lindenberger and Walter S. Wyatt, medical officers, have reported at headquarters in compliance with orders from the War Department, and have been temporarily assigned to the base hospital. They came from Camp Shelby at Hattiesburg, Miss.

The second evening session of the Kentucky State Medical Association was devoted to a military symposium. The special speaker was Dr. George Loewy, representing the French Army, who showed a number of slides of wounds, before, during and after treatment by the Carrel-Dakin method. Lieutenant Holstein read a paper on cerebrospinal meningitis; Major Jump of Philadelphia, from the Surgeon-General's Office, made an impassioned plea for more recruits for the Medical Reserve Corps; Major Poust told of the work of the Sanitary Corps at Camp Zachary Taylor, and Lieut.-Col. John Allen gave a summary of the work of the reviewing board.

Lieut. Willard J. Stone, contract surgeon, left for his home in Toledo, Ohio, on special leave, to return on call from the camp division surgeon.

Eighty-Seventh Division, Camp Pike, Little Rock, Ark.

With the exception of the base hospital, practically all the buildings at Camp Pike have their heating plants in good working order. The men both in barracks and in the officers' quarters were very comfortable during the recent cold spell.

Men leaving here for National Guard camps in the South, as they have been doing in large numbers for the past few weeks, did not depart with any special enthusiasm, knowing that they were leaving the land of heated wooden barracks and hot shower baths for a country of tents and "cold gray dawns" with no heat.

There is a feeling of great relief that the War Department's ban on reserve corps commissions has apparently been lifted, as commissions are beginning to arrive, notice of the recommendations for which were issued just prior to the institution of the embargo.

There are at Camp Pike nearly 200 medical officers, including those at the base hospital. A large percentage of these are from the training camps at Forts Riley and Oglethorpe.

PROMOTIONS

Many of these officers have been in the service nearly six months. The five promotions recently reported in these columns are from the last class, and are the only promotions received in this class at this camp. Promotions for medical men in this cantonment have not averaged 5 per cent. to date since the cantonment was opened. It is generally conceded that the matter of promotion of medical officers has not been overdone.

Many entered the service with a sort of unofficial understanding that they would be promoted at the end of ninety days' active service. The members of the old Medical Reserve Corps who were the first to enter the service, without the stimulation of whose example it would have been more difficult to get things started, are apt to feel that their claims for recognition should be considered before those who came in later. It is generally recognized, however, that under the tremendous pressure of the great work essential to the building up, officering and equipping of the Medical Department of so great an army, it is difficult to be absolutely fair to all concerned.

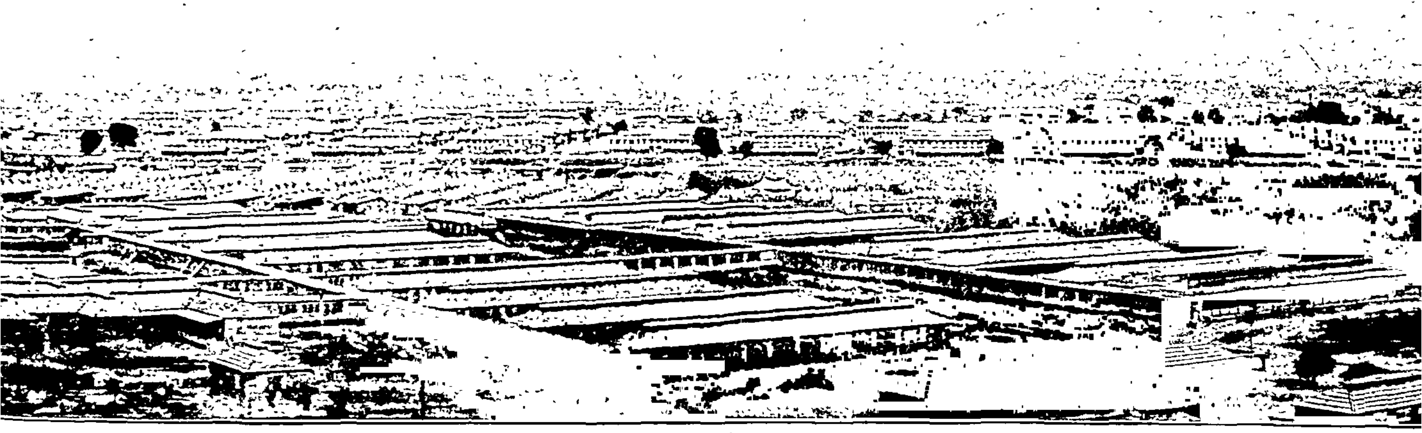
LECTURES

Lieut.-Col. Robert M. Thomburgh, division surgeon, gave an interesting and illuminating lecture on customs of the service at a lyceum held at the base hospital on the evening of November 5. Colonel Thomburgh brought out clearly that there are a good many things not covered by army regulations which are still important to know if the new medical man wishes to conduct himself as an "officer and a gentleman" while on duty.

Lieut. E. T. Wentworth of the orthopedic staff at the base hospital gave a series of three lectures on the foot recently at the officers' lyceum. Lieutenant Wentworth divided the subject by lectures into anatomy, diagnosis and treatment.

MEASLES

The measles epidemic at Camp Pike continues unabated. There was an apparent lull in the contagion for a short period, but at present there is a large number of these cases. The base hospital has found it too great a burden to look after them, so an order has been issued requiring each area to take care of its own cases as long as they are of the mild type without serious complications.



rman, Chillicothe, Ohio.

HEMORRHAGIC SEPTICEMIA OF MULES

An epidemic of hemorrhagic septicemia has kept the veterinary section of the Medical Reserve Corps, stationed at Camp Pike, busy for some time past. A quarantine covering several weeks has just been partially lifted at the auxiliary remount depot, the sanitary train receiving this week part of its quota of mules. There are over 10,000 animals at the remount depot. The deaths from hemorrhagic septicemia have totaled about 200. The serum treatment was used as a prophylactic in combating the disease.

ORDERS TO OFFICERS OF THE MEDICAL CORPS

Col. PERCY M. ASHBURN, Major SAMUEL S. CREIGHTON, Major CONDON C. McCORMACK, relieved at Fort Benjamin Harrison, Ind., and to proceed *to Washington, D. C.*, for duty in the office of the Surgeon-General of the Army.

To Camp Greenleaf, Fort Oglethorpe, Ga., for duty as instructors, from Fort Benjamin Harrison, Ind., Lieut.-Cols. A. W. SHOCKLEY, GEORGE H. SCOTT; Majors JOSEPH E. BASTION, TAYLOR E. DARBY.

To Fort Riley, Kan., as instructors, from Fort Benjamin Harrison, Ind., Lieut.-Col. HENRY F. PIPES, Major HOWARD McC. SNYDER.

Col. WILLIAM STEPHENSON, Headquarters, Central Dept., Chicago, Ill., *to Governors Island, N. Y.*, for duty as department surgeon.

Col. HENRY I. RAYMOND, Medical Supply Depot, Fort Mason, Calif., *to Chicago*, for duty.

Lieut.-Col. WILLIAM A. POWELL, relieved at Camp Custer, Battle Creek, Mich., and *to Camp Devens*, for duty as division surgeon.

To be relieved from Philippine Dept. and *to San Francisco*, and *to Western Dept.* for assignment to duty, Majors LANPHEAR W. WEBB, ALEXANDER W. WILLIAMS.

Major LEOPOLD MITCHELL, relieved from Hawaiian Dept. and *to San Francisco*, Western Dept., for assignment to duty.

Major JOHN P. FLETCHER, now on duty at Motor Ambulance Supply Depot, Louisville, Ky., be directed to proceed on completion of his present work at that place, of inspecting motor ambulance spare parts equipment, to Pontiac, Mich., for the purpose of inspecting motor ambulance equipment, and on completion of this duty to return to his proper station.

Col. GEORGE E. BUSHNELL to the following named camps for the purpose of inspecting the work of tuberculosis examiners, Camp Beauregard, Camp Pike, Camp Funston, Camp Dodge, Camp Grant.

Col. LOUIS A. LAGARDE, *to New York City* to present eight lectures on military medicine and camp sanitation, and additional lectures on military surgery at the University and Bellevue Hospital Medical College, New York University.

Lieut.-Col. GEORGE F. JUENEMANN, relieved at the Reorganization Camp, Gettysburg, Pa., and *to Fort Logan H. Roots, Ark.*, for duty as commanding officer of that post.

Col. ALLEN M. SMITH, at Fort Logan, Colo., *to inspect property known as the Westminster College, Westminster, Colo.*, with a view to reporting upon its desirability for use as a hospital.

Lieut.-Col. FRANK C. BAKER, relieved at Fort Oglethorpe, and to report to the commanding officer, *Camp Greenleaf*, for duty as commanding officer, Evacuation Hospital No. 4.

Lieut.-Col. PAUL C. HUTTON, relieved at Philippine Dept. and *to Camp MacArthur, Waco, Texas*, for duty as division surgeon.

Major LOUIS H. HANSON, relieved at Syracuse, New York, and *to Camp Bowie, Fort Worth, Tex.*, for duty as commanding officer of the base hospital.

Major GARFIELD L. McKINNEY, relieved at Corozal, Canal Zone, and *to commanding general, Eastern Dept.*, for duty.

Major LEARTUS J. OWEN, now on duty in the office of the Surgeon-General of the Army, *to Army Medical School, Washington, D. C.*, for examination for promotion.

Lieut.-Col. JOHN W. HANNER, relieved from 76th Division, Camp Devens, Ayer, Mass., and *to Washington, D. C.*, and report in person to the Surgeon-General of the Army for duty in his office.

Col. HENRY D. SNYDER, *to New York City* for temporary duty pertaining to the assembling of the branch of the Division of Finance and Supplies for duty overseas.

To San Francisco, Calif., and to report by wire to the Adjutant-General of the Army and to the Surgeon-General of the Army for further orders, from Hawaiian Dept. Majors CLARENCE R. BELL, GEORGE R. CALLENDER, HARRY N. KERNS.

Major WILLIAM H. TEFFT, relieved at Fort Douglas, Utah, and *to Fort Riley, Kan.*, for duty as commanding officer of Evacuation Hospital No. 7.

Lieut.-Col. ROBERT E. NOBLE, *to Camp Greenleaf* for duty in connection with the Medical Dept. and upon completion of this duty will return to his proper station.

Col. WALTER D. McCAW, relieved at Headquarters, Southern Dept. Fort Sam Houston, Texas, and *to Presidio, San Francisco, Calif.*, to assume command of the expedition of medical officers for duty overseas.

Col. CHARLES LYNCH, relieved with Base Hospital No. 2, Fort Bliss, Texas, *to Fort Sam Houston, Texas*, and report to the commanding general, Southern Dept., for duty as department surgeon.

Col. HENRY A. WEBBER, relieved at Laredo, Texas, and *to Fort Bliss, Texas*, for duty as commanding officer of Base Hospital No. 2.

Lieut. EDGAR N. HUME, relieved at the United States Disciplinary Barracks, Fort Leavenworth, Kan., and *to Washington, D. C.*, and report in person to the Surgeon-General of the Army for duty in his office.

ORDERS TO OFFICERS OF THE MEDICAL RESERVE CORPS

Alabama

To Army Medical School, from Fort Benjamin Harrison, Lieut. JULIAN E. MEYER, Birmingham.

To Camp Dix, Wrightstown, N. J., from Fort Ethan Allen, Lieut. GEORGE C. KILPATRICK, Mobile.

To Fort Riley, base hospital, Lieut. RUSSELL CALLEN, Birmingham.

To Hoboken, N. J., as officer in charge of Mobile Laboratory, 41st Division, Lieut. JAMES R. BEAN, Birmingham.

To Rockefeller Institute, New York City, for instruction, from Fort Oglethorpe, Lieut. JOHN D. DICKSON, Birmingham.

Arkansas

To Camp McClellan, Anniston, Ala., base hospital, from Fort Oglethorpe, Lieut. JAMES F. POE, Shirley.

To Fort Sam Houston, Tex., from Fort Benjamin Harrison, Lieut. GEORGE B. FLETCHER, Little Rock.

To home and inactive list, from Fort Des Moines, Lieut. DANIEL W. JONES, Little Rock.

California

To Berkeley, Calif., University of California, as recruiting officer, Lieut. BRUNO F. SANDOW, Oakland.

To Camp Kearney, Linda Vista, Calif., base hospital, Capt. HERBERT S. THOMSON, Berkeley.

To Chicago, Ill., Northwestern University Dental School, for instruction, and on completion *to Camp MacArthur,* base hospital, from Fort Oglethorpe, Capt. ERNEST DOZIER, Redding; for instruction and on completion *to proper station,* from Camp Lewis, Lieut. JOSEPH R. BROWN, San Francisco.

To Fort Leavenworth, Kan., for duty in the department laboratory. Capt. JAMES M. FISHER, Gilroy.

To Fort Sam Houston, Tex., from Fort Benjamin Harrison, Lieuts. LOUIS FELGER, PERCY K. TELFORD, Los Angeles; WILLIAM A. BOYLE, FRANK W. PINGER, San Francisco.

To Los Angeles, Calif., for instruction in military roentgenology, from Presidio of San Francisco, Lieut. WALLACE A. REED, Covina.

To San Francisco, Calif., for duty, Lieuts. WALTER E. COPPEDGE, Alturas; ALBERT F. ADAMS, Sacramento; *to Letterman Hospital,* for duty, from the Presidio of San Francisco, Lieut. HARRY E. FOSTER, Berkeley.

Colorado

To Camp Grant, Rockford, Ill., base hospital, from Fort Oglethorpe, Lieut. WILLIAM A. SEDWICK, Denver.

To Rockefeller Institute, New York City, for instruction in laboratory work, from Houston, Texas, Lieut. EDWARD P. COOKE, Milwaukee.

Wyoming

To Rockefeller Institute, for instruction in laboratory work, Lieut. GEORGE W. EARLE, Lusk.

Association News

MEDICAL ADVISORS TO THE GOVERNORS OF STATES

Physicians Selected for the Purpose of Establishing and Conducting the Work of the Medical Advisory Boards in Connection with the Selective Service Regulations

Under date of October 19, the following report of the Board of Trustees was submitted to the members of the House of Delegates of the American Medical Association, and was adopted unanimously by a postal vote:

To the Members of the House of Delegates of the American Medical Association:

Under date of Oct. 13, 1917, Hugh S. Johnson, Lieutenant-Colonel, Judge Advocate, Executive Officer of the Provost Marshall General, acting for the President of the United States and War Department, addressed a letter to the American Medical Association from which we quote:

"We need the active and vigorous cooperation of the American Medical Association. We need the promptest and most thorough action in this regard. Will you not call together a sufficient number of your executive council to authorize this cooperation by the Association, and to consider a definite and concrete proposition which can be presented here, and upon which we can act?"

Specifically, the cooperation desired of the Association is set forth in the following:

"It is planned to establish Medical Advisory Boards, not necessarily integrated with the territorial jurisdiction of either Local or District Boards, but having headquarters with sufficient apparatus and conveniences so located as to be accessible to boards in the portion of the state in which the Advisory Boards are situated. Any case in which the local examining physician has held the registrant disqualified for service (unless the disqualification is obvious) or in which the local physician is in doubt, or in which the registrant feels aggrieved by the decision of the local physician, or where the Local Board or the Government Appeals Agent desires to appeal the findings of the local physician, is to be sent to such Medical Advisory Board for an exhaustive [medical] reexamination upon which the Local Board can proceed to a final determination."

These Medical Advisory Boards will consist of physicians selected for their ability to make thorough and complete physical and mental examinations. This means that the boards shall be composed of specialists competent to make such laboratory and other examinations as may be required. This matter was of such importance and the urgency was so great that, in accordance with the spirit of the recommendation of the Reference Committee on Reports of Officers adopted by the House of Delegates in June, 1917, i. e.:

"We further suggest to the House of Delegates that it formally and officially offer to the government, through adoption of this recommendation, the services and facilities of the American Medical Association for such assistance as may be in its power to render hereafter."

the Board of Trustees, on Oct. 19, 1917, in special session assembled for the purpose of considering the matter, all the members being preser unanimously adopted the following resolutions:

Resolved, That the Board of Trustees for and on behalf of the Ame ican Medical Association accept the invitation to cooperate with t Provost Marshall General in the matter presented in the letter of Lieu Col. Hugh S. Johnson under date of Oct. 13, 1917.

Resolved, That a committee of three be and hereby is appointed wi full power to act in conjunction with the Provost Marshall-General the premises.

The following committee was appointed: M. L. Harris, secretar Board of Trustees; Hubert Work, chairman, House of Delegates, a E. J. McKnight, member of the Board of Trustees.

Respectfully submitted, by order of the Board of Trustees,

M. L. Harris, Secretary, Board of Trustees.

The committee at once proceeded to Washington, D. After consultation with Lieut.-Col. Johnson of the Provo Marshal-General's Office, a conference with representatives the Committee on State Activities of the General Medic Board of the Advisory Commission, Council of Nation Defense, was arranged. At the latter meeting, Drs. Edwa Martin, Philadelphia, F. F. Simpson, Pittsburgh, and Jol D. McLean, Philadelphia, were appointed a committee fro this Committee on State Activities to cooperate with the cor mittee of the American Medical Association, and it w agreed that the six should select a seventh member of th joint committee.

The joint committee met in Washington, D. C., Novemb 1, when on motion of Dr. Edward Martin, Dr. Alexander Craig, secretary of the American Medical Association, w named as the seventh member and made secretary of t joint committee. On motion of Dr. Hubert Work, Dr. Edwa Martin was elected chairman.

The committee was advised that the Provost Marsha General desired to have the joint committee immediately su gest in each state a member of the Medical Reserve Corp not assigned to duty in connection with the National Arn or base hospital, in order that the Surgeon-General of t Army might be requested to order this medical officer in active duty as the medical adviser to the governor of his sta in the erection of the medical advisory boards for the sta The joint committee thereupon proceeded to select a physici in each state to be recommended to act as medical adviser the governor.

Later, the members of the committee received the followi telegram:

You have been appointed a member of committee on Medical Appe Boards of General Medical Board of Council of National Defense. Y are requested to attend an important meeting of this committee at t Council of National Defense, Washington, 11 o'clock, Friday, Nove ber 16.

Franklin Martin, Chairman, General Medical Board.

In compliance with this request, the joint committee m Dr. John D. McLean, secretary of the Committee on Sta Activities of the General Medical Board of the Advisory Con mission, Council of National Defense, reported to t joint committee that it had been necessary to revise the li of medical advisers to the governors, who had been suggest at the previous conference of the joint committee. A numb of such changes had to be made for different reasons, amor which were that the physician selected was on duty elsewher or was connected with a hospital unit, or was an officer his own state. Accordingly, Dr. McLean reported that t following physicians had been selected as medical advise to the governors and requested to report for a conference be held on Saturday, November 18:

Alabama	James Norment Baker, Montgome
Arizona	Francis Eppes Shine, Bisb
Arkansas	Clinton P. Meriwether, Little Ro
California	Henry Howard Sherk, Pasade
Colorado	Horace C. Wetherill, Denv
Connecticut	David Chester Brown, Danbu
Delaware	James A. Draper, Wilmingt
District of Columbia	John Wesley Bovee, Washingt
Florida	Carey Pegram Rogers, Jacksonvil
Georgia	William Clifton Lyle, Augus
Idaho	Warner Hunter Carithers, Mosco
Illinois	Frank Billings, Chica
Indiana	Joseph Rilus Eastman, Indianapol
Iowa	William Wilson Pearson, Des Moin
Kansas	John Franklin Hassig, Kansas C
Kentucky	Louis Samuel McMurtry, Louisvi

Louisiana	Charles Jefferson Miller, New Orleans
Maryland	William Henry Welch, Baltimore
Massachusetts	Fred Lund, Boston
Michigan	Reuben Peterson, Ann Arbor
Minnesota	William James Mayo, Rochester
Mississippi	Walter B. Dobson, Jackson
Missouri	John Young Brown, St. Louis
Montana	Thomas Casey Witherspoon, Butte
Nebraska	August Frederick Jonas, Omaha
Nevada	George McKenzie, Reno
New Hampshire	John Martin Gile, Hanover
New Jersey	Philip Marvel, Atlantic City
New Mexico	John Wilson Elder, Albuquerque
New York	Charles North Dowd, New York
North Carolina	John Wesley Long, Greensboro
North Dakota	Victor Hugo Stickney, Dickinson
Ohio	Charles S. Hamilton, Columbus
Oklahoma	Claude A. Thompson, Muskogee
Oregon	Kenneth Alexander J. MacKenzie, Portland
Pennsylvania	Edward Parker Davis, Philadelphia
Rhode Island	John William Keefe, Providence
South Carolina	Robert Spann Cathcart, Charleston
South Dakota	Fred Angier Spafford, Flandreau
Tennessee	William D. Haggard, Nashville
Texas	Witten Booth Russ, San Antonio
Utah	William Brown Ewing, Salt Lake City
Vermont	John Brooks Wheeler, Burlington
Virginia	Reid White, Lexington
Washington	James R. Yocum, Tacoma
West Virginia	John Egerton Cannaday, Charleston
Wisconsin	L. Rock Sleyster, Waupun
Wyoming	Fred Wood Phifer, Wheatland

The duties of these state medical advisers and of the medical advisory boards were explained by Provost Marshal-General Crowder and Lieut.-Col. Hugh S. Johnson of the Provost Marshal-General's Office. The medical advisers were directed to report to the governors of their state and to offer to assist him in determining the number of districts and territory to be covered by each district as well as in the selection of the personnel of the medical advisory boards.

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest; such as relate to society activities, new hospitals, education, public health, etc.)

CALIFORNIA

County Medical Society Aids War Sufferers.—The Fresno County Medical Society at its meeting, November 6, voted the establishment of a permanent monthy donation of $10 to be turned over to relieve the sufferers from the war in Europe.

New Officers.—The Psychopathic Association of California, at its annual meeting at Los Angeles, November 3, elected Curtis D. Wilbur, president; Edward H. Williams, vice president; William S. James, secretary-treasurer, and Drs. Henry G. Brainerd, Charles L. Allen, Edward H. Williams and Thomas J. Orbison, all of Los Angeles, as medical members of its board of directors.

Personal.—Dr. Everett R. Smith, Los Angeles, is reported to be seriously ill at the California Hospital, Los Angeles. ——Dr. Charles W. Anderson, Los Angeles, has returned after a year's service with the Canadian Army Medical Corps on the western front.——Dr. John T. Davison, Stockton, has been reappointed health officer of San Joaquin County.——Dr. Nathaniel B. Potter, formerly of New York, has transferred his work regarding the metabolic unit to Santa Barbara, where he will continue his research work at the Cottage Hospital.——Dr. Stanley Stillman, San Francisco, has received orders for foreign service.——Dr. Franklin S. Wilcox, Patton, superintendent of the Southern California State Hospital, has been appointed superintendent of the State Hospital at Norwich, Conn., succeeding Dr. Harry Pollack.

ILLINOIS

German, Not General.—At the meeting of the German Hospital Association, held November 15, the question of changing the corporate name of the institute from "The German Hospital of Chicago" to "The General Hospital of Chicago" was voted down, and the institution will retain its original name.

Reconstruction Service.—In the report of the Central Free Dispensary of Rush Medical College it is stated that the reconstruction of invalided soldiers and men and women physically unfit who are needed in the industries will constitute an important part of the work of the institution during the coming year. Eighteen members of the staff of the dispensary are now in the army service.

Personal.—Major William J. Swift, Chicago, commanding the Field Hospital Section of the Thirty-Third Division, Camp Logan, Houston, Texas, has resigned, and his resignation has been accepted to take immediate effect.——Major Eugene G. Clancy, Chicago, formerly of the Seventh Illinois Infantry, and later commander of the One Hundred and Thirtieth Field Hospital, has been appointed Major Swift's successor.——Dr. Clifford C. Ellis, formerly a member of the staff of the Chicago State Hospital, Dunning, has been appointed assistant superintendent of the Watertown State Hospital, succeeding Dr. Edward A. Foley, transferred to similar duty at the Chicago State Hospital.——Dr. Joseph B. Liston, Carlinville, has been appointed a member of the staff of the Jacksonville State Hospital.——Dr. Martin L. Moyer, Hillsboro, was operated on in the Hillsboro Hospital, November 2, for nephrolithiasis, and is reported to be doing well.

IOWA

Field Hospital Unit Formed.—Dr. Francis L. Love, Iowa City, has completed the organization of the Iowa Field Hospital Unit, which he will command. His officers are Drs. Virgil Orin Muench, Nichols; Philip M. Day, Barnes City, and Arthur T. Bailey, Iowa City.

Personal.—Dr. Richard H. Whalen, Tama, has been appointed physician and surgeon to the Sac and Fox Indian Agency, succeeding Dr. Benjamin Thompson.——Dr. Alexander W. Trout, Perry, received a check for $8,000 from Washington, D. C., November 1, on account of services rendered during the Civil War.——Dr. James B. Horner, Lamoni, who suffered a cerebral hemorrhage, October 25, is reported to be improving.——Fire in the office of Dr. George A. Carson, Mount Vernon, October 23, burned out the entire interior of the building.

Hospital News.—At a special meeting of the stockholders of the May Hospital Company in Charles City, October 30, it was voted that the corporation be dissolved.——Miss M. Esther Bayliss, Minneapolis, has been appointed superintendent of the Spencer Hospital, succeeding Miss Della Darling, resigned to take up Red Cross duties in France.——Work has been commenced on the new Children's Hospital in connection with the State University of Iowa, Iowa City, which is to be situated on the West Side of the Iowa River. An appropriation of $150,000 for this institution was made by the last legislature.——The Denison (Iowa) Hospital, announces that it is now thrown open to all physicians.

KENTUCKY

Sanatorium Nearly Full.—Dr. Howard E. LeCates, physician in charge of the Fayette County Tuberculosis Sanatorium, states that there are now fifty patients in the institution, which is within two of its capacity.

New Officers of State Association.—At the sixty-seventh annual meeting of the Kentucky State Medical Association, held in Louisville, November 6 to 9, the following officers were elected: president, Dr. James S. Lock, Barboursville; vice presidents, Drs. Joseph L. Barker, Pembroke; Hazelton H. Stallard, Pikeville, and James C. Douglass, Franklin; councilors, third district, Dr. Joseph N. McCormack, Bowling Green; sixth district, Dr. Robert C. McChord, Lebanon, and ninth district, Dr. James W. Kincaid, Catlettsburg, and delegates to the American Medical Association, Drs. William W. Richmond, Clinton, and Carl L. Wheeler, Lexington (reelected).

LOUISIANA

Infant Clinic.—A free clinic for infants up to the age of 9 months has been established at the Lying-In Hospital, New Orleans. The clinic will be in charge of Dr. George Bloom, and will be open from 11 to 12 o'clock daily.

Personal.—Dr. William H. Robin, superintendent of the New Orleans City Board of Health, was given a handsome gold badge by the employees of his department, November 3.——Dr. George W. Martin, Arnaudville, was made superintendent of oil inspection by the state board of health, October 29.——Dr. Thaddeus P. Bell, New Orleans, has been elected field secretary of the Louisiana Anti-Tuberculosis League for the coming year.——Asst. Surg. Howard F. Smith, U. S. P. H. S., has been appointed, by the president of the state board of health, director of the civil sanitary district surrounding the Thirty-Ninth Division Army Camp.——Dr. Ernest S. Lewis, New Orleans, has been appointed consulting gynecologist; Dr. Charles Chassaignac, consultant in genito-urinary diseases, and Dr. Roy M. Van Wart, psychiatrist, to Charity Hospital, New Orleans.

MARYLAND

Diphtheria at Fullerton.—There has been one fatal case of diphtheria at Fullerton, Baltimore County, and considerable anxiety exists among the parents of children there. Dr. Harry M. Slade, Reisterstown, county health officer, will have all cases of the disease which may develop isolated, and every precaution will be taken to prevent an epidemic.

Personal.—Dr. Lewellys F. Barker, Baltimore, was elected president of the Southern Medical Association at the annual meeting of the association held in Memphis, Tenn.——Dr. Franklin P. Mall, professor of anatomy in the medical department of the Johns Hopkins University, a nationally known authority on anatomy and author of several textbooks on the subject, is critically ill at the Johns Hopkins Hospital, following two operations to remove gallstones.

MICHIGAN

New Hospital.—A new fireproof contagious disease hospital, to cost about $12,000, is to be erected by the St. Luke's Hospital Association, Marquette.

Personal.—Dr. John C. Lampman, Hastings, injured his hip seriously by a fall from a stepladder, November 7.——Dr. Frederick C. Warnshuis, Grand Rapids, chief surgeon of the Pere Marquette System, fractured his leg in a collision between his automobile and another car, November 5.

Health League Recommended.—In his address, made on retiring from the presidency of the Michigan Anti-Tuberculosis Association, Dr. Arthur F. Fischer, Hancock, chief of the medical staff of the Quincy Line, recommended the establishment of a Good Health League, which would come closer to the people than an antituberculosis association could.

MISSOURI

Goodwin and Dercle in St. Louis.—Col. T. H. Goodwin of the British Army Medical Service and Col. C. U. Dercle of the French Army Medical Service were guests of the Medical Section of the State Committee on National Defense at St. Louis, November 16. They delivered addresses before the Chamber of Commerce and the City Club at a luncheon, were enteretained at a dinner at 6 o'clock at the St. Louis Club, and at 8 o'clock adressed a large audience in the Central High School. Colonel Dercle addressed the St. Louis Medical Society, November 17.

Reports of Births.—For failure to report the birth of a child, a St. Louis doctor who had knowledge of the birth was arrested and fined $5, the midwife who delievered the child was fined $10. The baby is blind. After birth the baby developed inflamed eyes which the midwife treated for nine days and then called the physician, who was unable to save the eyes, and failed to report the birth. Commenting on this neglect the St. Louis *Post Dispatch* remarks editorially: "In the light of these facts, we venture the opinion that St. Louis should make an effort to keep as perfect a record of new babies as it does of new corpses."

Personal.—Dr. J. Carl Drake, formerly of St. Louis, now lieutenant in the One Hundred and Thirty-Eighth Infantry (Fifth Missouri) has been confined to the base hospital, Fort Sill, Okla., for several weeks. He was operated on November 1, and will soon be able to resume work in camp.——Dr. E. H. Trowbridge, physician at the tuberculosis hospital and municipal farm of Kansas City, has been elected secretary of the hospital and health board of Kansas City, and will be in charge of the medical inspection of the schoolchildren.——Dr. Guy L. Noyes, dean of the Medical School, University of Missouri, has been relieved from military duty at Camp Funston and returned to Columbia to continue his school duties.——Dr. William W. Duke, Kansas City, was a guest at a joint meeting of the St. Louis Medical Society and the St. Louis Dental Society, November 3, and delivered an address on "Dental Sepsis as a Focal Infection."

MONTANA

Scarlet Fever.—On account of the prevalence of scarlet fever in Helena, a meeting of state and county health officials was held in that city, October 26, at which it was decided to take stringent measures to stamp out the disease. Dr. John H. Dent, East Helena, was appointed deputy county health physician to assist the county physician with the scarlet fever cases.

Hospital Notes.—At the meeting of the board of trustees of the Butte Deaconess Hospital Association, October 31, contracts were signed for an addition to the present building to cost $21,500, and to accommodate forty patients.——The Grandview Hospital, located just outside the city limits of Malta, was destroyed by fire, October 24. All patients were safely removed from the institution.

Personal.—Dr. Herbert H. Judd, Bozeman, has been appointed a member of the State Board of Medical Examiners, succeeding Dr. William L. Renick, Butte, resigned.——Dr. Julius H. P. Gauss, Lewistown, has been nominated by the administrative board of the Mayo Clinic, Rochester, Minn., for a fellowship in internal medicine in the Mayo Foundation.——Dr. Oscar M. Lanstrum, Helena, has been elected a vice president, and Drs. Thomas C. Witherspoon, Butte, and William F. Cogswell, Helena, members of the executive board of the Montana State Association for the Study and Prevention of Tuberculosis.

NEBRASKA

Friction in State Board.—The state board of health, October 19, made an investigation of the friction in the administration staff of the board. Health Commissioner Tenney, Mrs. Andrews, the statistician, and Dr. William F. Wild, state epidemiologist, are said to be involved in this investigation.

Personal.—Dr. Benjamin F. Williams, superintendent of the Lincoln State Hospital for the Insane, presented his resignation to take effect Jan. 1, 1918, and will enter private practice in Lincoln.——Dr. William J. Davies, Fremont, who was operated on for the removal of gallstones in the Nicholas Senn Hospital, Omaha, October 31, is reported to be making satisfactory progress toward recovery.

NEW YORK

New York City

The Harvey Society.—The second of the present course of Harvey Society lectures was given at the New York Academy of Medicine, November 24, by Dr. Linsly R. Williams, on "Medical Problems of the War."

In Memory of Dr. Lewis Atterbury Stimson.—Exercises in honor of the memory of Dr. Lewis Atterbury Stimson, professor of surgery in Cornell University Medical College, were held in the auditorium of the college, November 16. Addresses were made by Dr. Jacob Gould Shurman, Elihu Root, Dr. W. Gilman Thompson and Dr. Edward L. Keyes.

Representatives of Red Cross Meet.—A meeting of representatives of the Southern Section of New York met in this city recently for the purpose of stimulating the war work and adding to the efficiency of the Atlantic Division. Dr. Thomas D. McRossie, Brooklyn, member of the Red Cross Commission to France, addressed the representatives. He laid special stress on the necessity of keeping up the work of making surgical dressings.

Personal.—Dr. J. Ramsay Hunt has been appointed associate in neurology and psychiatry on the staff of the New York City Children's Hospital and School, Randall's Island.——Dr. William M. Leszynsky has been appointed neurologist to the Manhattan State Hospital.——Drs. Morris Steinberg and Leo Lieberman, members of the house staff of St. Mary's Hospital, Jamaica, were injured in a collision between the ambulance in which they were riding and an automobile. November 9.——Dr. Thomas F. Reilly has been appointed to the chair of medicine in the Fordham University School of Medicine.

Laboratory Course for War Service.—Through the united efforts of the War Service Committee of the Medical Women's National Association, New York University, and the bureau of laboratories of the department of health, a course in medical laboratory work is offered to applicants who have the preliminary training in science and scientific methods obtained in a four years' college course or the equivalent. The object is to fit workers for war service in medical laboratories in this country and in Europe. The course will extend over a period of three months, requiring six hours' work each day. Application may be made to Dr. Anna W. Williams, Research Laboratory, foot of East Sixteenth Street. The fee is $75.

NORTH CAROLINA

Personal.—Dr. Charles T. Nesbitt, Wilmington, has been appointed health commissioner of Akron, Ohio.——Dr. William K. Reid has resigned as superintendent of the health department of Charlotte.

State Quarantine Law Enforced.—Seventy-seven counties of North Carolina have at present put into operation the new state quarantine law. Twenty-three counties have so far made no progress in this regard.

Orthopedic Hospital for Gastonia.—Mr. R. B. Babington, Gastonia, has donated 20½ acres of land on which is to be established an orthopedic hospital, the charter for which has already been granted by the state.

PENNSYLVANIA

Physicians Needed.—The Pennsylvania State Committee of the Council of National Defense, Medical Section, announces that the committee has applications at this time pending to fill the following positions in hospitals and institutions in or near Philadelphia: Medical: Superintendent of hospital, salary $1,500 per annum; two clinical assistantships, psychopathic, salary $600 per annum; assistant bacteriologist, salary $1,000 per annum; anesthetizer, salary $30 per month. Surgical: Assistant surgeon, salary $3,000 per annum; visiting surgeon, dispensary, no salary; visiting ophthalmologist, no salary; visiting laryngologist, no salary. Internships, general internships, resident physicians in special hospitals, etc. Applicants for these positions should communicate with the secretary, Charles Scott Miller, M.D., giving school and year of graduation, qualifications, credentials, etc., and salary desired.

Philadelphia

Addresses Before Medical Societies.—Dr. Rosalie Slaughter-Morton, New York, chairman of the Woman's Committee of the Council for National Defense, delivered an address on "War Service for Women Physicians" at the meeting of the Medical Society of the Woman's Hospital, November 20.——Dr. Arthur S. Kendall, Sydney, N. S., delivered the Gross Lecture, "Recent Developments in Intestinal Bacteriology," at the meeting of the Pathological Society, November 22.

Philadelphia County Medical Society.—At the meeting of the Philadelphia County Medical Society, to be held November 28, Major David Silver, Pittsburgh, assistant director of the Division of Military Orthopedic Surgery, will discuss the surgical aspects of the function of orthopedic surgery in the war, and will detail what has been accomplished and what his branch intends to do for the service. The civic aspects will be discussed by Major Henry R. Hayes of the Sanitary Corps. The discussion will be opened by Dr. Gwilym G. Davis, professor of orthopedic surgery in the University of Pennsylvania, and a member of the Orthopedic Advisory Council.

Optometrists to Be Ousted.—About 120 fake "eye-doctors" are to be thrown out of business shortly in this city. The unscrupulous individuals who have not hesitated to advertise themselves as optometrists, when they had no right whatever to that title, and who have ruined the eyes of thousands of their patients by prescribing glasses or giving treatment which was harmful in the extreme, will be ousted within a few months, if the plans of the State Board of Optometrical Education, Examination and Licensure are realized. There are about 2,000 practicing optometrists in Pennsylvania, 800 of whom have offices in this city. The state board today began examining the 800 local optometrists, 300 taking the prescribed examinations in the Central High School. Two more days will be required to examine the others. The examinations, which cover five subjects, are the first to be held under the new law to license men engaged in the practice of optometry, and are designed to eliminate the charlatan practitioner.

WISCONSIN

Tells of War Surgery.—At the meeting of the Beloit Six O'clock Club, November 14, Major Charles McDonald spoke on war surgery and Red Cross work in Austria-Hungary, where he has spent the last three years.

Anthrax in Milwaukee.—A second case of anthrax has been discovered in Milwaukee in the same tannery where the first victim was found. The infection is not so severe as in the first case, and the patient is under treatment in the South View Isolation Hospital.

All Physicians Medical Examiners.—The medical examinership for the Wisconsin State Tuberculosis Sanatorium has been extended to include all regularly licensed physicians who are citizens of Wisconsin. The former list will be used in cases in which the applicant for the sanatorium does not give the name of his family physician.

Hospital Items.—The Franson Hospital, Augusta, has been sold to Mr. Robert Reider, Humbird.——The fund-raising campaign for the Ashland General Hospital began, November 12. A tentative site for the tuberculosis sanatorium for the northern part of the state has been selected on the Bayfield County side of Chequamegon Bay. The last legislature passed a bill appropriating $75,000 for this project.

Personal.—Dr. Matthew N. Federspiel, Milwaukee, was elected president, and Dr. Henry McCabe, Milwaukee, vice president of the Marquette University Alumni Association.——Dr. Thaddeus D. Smith, Neenah, who was recently wounded in a German air raid in a base hospital behind the trench line, is under treatment in a hospital in England.——Dr. Angus E. MacMillan, Stevens Point, was operated on in Chicago for removal of the gallbladder, November 1, and is reported to be doing well.

New Officers.—At the annual meeting of the West Wisconsin District Medical Society, held in Eau Claire, Dr. Fred S. Cook, Eau Claire, was elected president; Dr. Nels Werner, Barron, vice president, and Dr. Eugene E. Tupper, Eau Claire, secretary.——At the annual meeting of the Wisconsin Anti-Tuberculosis Association, held in Milwaukee, November 9, the following officers were elected: president, Dr. Timothy L. Harrington, Milwaukee; vice presidents, Drs. John W. Coon, Stevens Point, and Charles D. Boyd, Kaukauna; recording secretary, Dr. J. Gurney Taylor, Milwaukee, and treasurer, Mr. J. H. Kopmeier.

CANADA

Hospital News.—Finance Commissioner Bradshaw, Toronto, and Medical Officer of Health Dr. Charles J. C. O. Hastings have made a joint report to the board of control that the boards of the several hospitals in that city be coordinated or else governed by a commission, with a general manager. Duplication of certain expenditures is costing the city thousands of dollars. The city contributes $900,000 annually to the hospitals and is not in a position to see how the money is being expended. Recently the hospitals have requested grants from the city treasury as follows: General, $50,000; Western, $20,000; Toronto Free Hospital for Consumptives, $40,000; Hospital for Sick Children, $38,000, and Women's College Hospital, $33,000. The two officials recommended that the grant to the General Hospital be conditioned on the government of Ontario making a grant of $25,000; that the grant to the Western be $11,182; that the Hospital for Consumptives get the full amount of $40,000 asked for; that the full amount asked be paid the Hospital for Sick Children, and that the grant to the Woman's College Hospital be deferred until after the war, as the money was to be used for the erection of a new wing.

Personal.—Dr. Charles Sheard, sometime medical officer of health, Toronto, and formerly professor of preventive medicine in the University of Toronto, has been chosen to contest South Toronto constituency in the pending federal elections.——Dr. S. Hawden, who has been in charge of the Dominion government laboratory, Agassiz, B. C., has been appointed dominion pathologist in succession to Dr. Charles P. Higgins, Vancouver, who has resigned to enter business.——Dr. Allen M. Baines, Toronto, addressed the graduating class of nurses at the Hospital for Sick Children, November 16. He emphasized the importance of nurses being good readers, maintaining that elocution should be part of their course, inasmuch as reading is a source of very great pleasure to a patient in a convalescent stage.——Lieut.-Col. Clarence L. Starr, Toronto, who has been doing orthopedic work in England for a year, has returned to Toronto. In a short address to the nurses of the Hospital for Sick Children he spoke of how splendidly the nurses graduated from that hospital had upheld the honor of the hospital in France and England.——Major Harley Smith, home for a short furlough in Toronto, will shortly return to England and will probably be attached to a hospital in France, as Major Smith speaks French and Italian fluently.——Lieut.-Col. Charles H. Gilmour, Toronto, is now surgeon-in-chief, Ontario Military Hospital, Orpington, England, Lieut.-Col. William J. O. Malloch, Toronto, having been transferred to the hospital at Basingstoke.——Capt. J. Harvey Todd, Toronto, who has been overseas nearly three years, has returned to Quebec, and is now with Militia Headquarters as A. D. D. A. M. S., fifth district. His services abroad have been recognized by promotion to the rank of major.——Dr.

George C. Livingstone, who for the past year has been assistant superintendent of the Toronto General Hospital, has severed his connection with that hospital, and has offered his services for overseas. For a time he will be attached to the C. A. M. C., Exhibition Camp, Toronto.

GENERAL

Hospital Car.—A hospital car made at the suggestion of Dr. David O. Edson, New York, to transport sick and injured soldiers from the cantonments to base hospitals has just been completed by the mechanical department of the Erie Railroad. This car will accommodate twenty-eight patients, and has on each side seven two-tier berths.

Southern Tuberculosis Fighters Meet.—At the annual meeting of the Southern Tuberculosis Conference, held at the Pine Breeze Sanatorium, Chattanooga, Tenn., the following officers were elected: president, John Stagmier, Chattanooga, Tenn.; vice president, Boulton Smith, Memphis; members of the executive committee, Drs. Augustus C. Shipp, Little Rock, Ark.; William H. Cox, Jacksonville, Fla.; Henry Boswell, Jr., Magee, Miss.; Lewis B. McBrayer, Sanatorium, N. C.; William N. Lackey, Gallatin, Tenn., and directors, Drs. David L. Flanary, Dyersburg, Tenn., and Henry P. Coile, Knoxville, Tenn.

Insurance Company Offers Vital Statistics.—The statistical bureau of the Metropolitan Life Insurance Company invites physicians, public health and social workers to make use of its collection of mortality statistics. These statistics present the principal causes of death among white and colored wage earners in the United States and Canada. The material covers over 10,000,000 individuals for each of the six years, 1911 to 1916. Death rates are available for each race, by sex and by age period. All inquiries should be addressed to Statistical Bureau, Metropolitan Life Insurance Company, 1 Madison Avenue, New York City.

FOREIGN

Training School for Women Workers.—Through the efforts of Mr. Edouard Herriot, mayor of Lyon, France, a professional training school for the higher technical development of women has been established and opened its first session, Oct. 1, 1917. The curriculum of the school will include a commercial course and a technical course of two years each. The minimum age limit for entrance has been fixed at 16 years, and an examination for admission will be required. An elaborate course of study in commercial and technical subjects has been provided.

In the munition plants of the city, in May, 1917, out of a total of 12,000 workers, more than 50 per cent. were women. Efforts are constantly being made to improve the surroundings of the women and to make the work congenial. Hygienic conditions are being improved and rest rooms provided. Extra holidays will be granted the women, and expectant mothers are made an allowance of 4.50 francs per day, for a period of forty days, making a total allowance of about $36. If both father and mother are employed in any plant, the children are cared for during working hours by especially organized asylums. The women workers are divided into two squads, one working from 6:15 a. m. to 2:15 p. m., with an interruption of 45 minutes for luncheon, the second squad working from 2:30 to 9:30 p. m., with the same interval for the evening meal.

LONDON LETTER

London, Oct. 30, 1917.

The War

ARRIVAL OF SECOND AMERICAN ORTHOPEDIC CONTINGENT

The second American orthopedic contingent, composed of forty-two medical officers under the direction of Major Goldthwaite, has arrived. All of the officers as well as three of engineering experience commissioned in the sanitary corps are to take charge of the development of curative workshops in the American orthopedic hospitals in France. There are also twelve orthopedic nurses as a nucleus around which a nursing staff is to be developed. All the medical staff except the director are to be distributed temporarily through the British orthopedic centers. Arrangements have been made by which these centers can be used for training Americans in orthopedic work with the idea of providing relief for the large number of medical officers that will be required for this special work. When these men are needed for service in the American hospitals in France, another group will be sent from home to take their place in the British hospitals. The rotation will be continued until the American hospitals are fully staffed. Major Goldthwaite is going on to American headquarters in France to organize the orthopedic hospital with the American Army.

FOOD CONTROL

All the principal foodstuffs have been brought under control, that is to say, bread, flour, meat, potatoes, sugar, tea, milk, butter, cheese and bacon. Control has further been extended to certain subsidiary foods, such as jam, oatmeal, dried peas and beans, chocolate and sweetmeats, and also to feeding stuffs for livestock. Prices have been or are being fixed at every stage of production and distribution of controlled commodities, from the stockyard or barn to the shop counter. The speculative middleman has been eliminated, and the charges that may be made by the necessary middleman and the retailer are being defined and regulated by the fixing of prices or profits. The prices to be paid for live cattle have been fixed on a descending scale, so as to show an ultimate reduction of from 20 to 25 per cent. Butchers' profits are limited to 5 cents per pound, or 20 per cent. on their fortnightly turnover, whichever is less. These measures should ultimately secure an average reduction in the retail price of meat equivalent to the reduction in the purchase price of cattle. As compared with last July, the wholesale price of British beef has fallen 17 per cent., and the wholesale price of mutton, 19 per cent. This fall is already reflected in retail prices, but some time must elapse before its influence can be fully ascertained. As a result, a guaranty to growers of $30 a ton on the acreage under potatoes has been considerably increased, and there is an abundant crop. The retail price of these is controlled, and as a rule will be about 2 cents per pound. Complaints have been made in regard to the distribution of sugar rather than to its price. A new scheme of sugar distribution is designed to secure that such supplies as are available shall be distributed without suspicion of favor. It safeguards the position of the householder, whether he be rich or poor. Sir Arthur Yapp, director of food economy, advocates simpler meals of two-courses only at midday or evening dinner, at any rate on three days of the week, and also extended use of communal kitchens. He suggests no butter or bread for midday or evening dinner, but extra vegetables in their place, no cream except for invalids and children; no tea except for tea meal, no open sugar bowl, and no ham or bacon except for breakfast. There must be better preparation of food by expert cooking. To obtain every possible assistance in the new campaign he is relying largely on the churches, but is hoping also for the help of cooperative societies and the friendly society organizations. Then he is bringing into effect an organization to be known as the League of National Safety, in which he aims first at enrolling 10,000 members, to be followed almost immediately by 100,000 and later by a million. Speaking of the difficulties of rationing, he said that anything of that kind might be good enough for Germany, but it was not quite English. He had unbounded faith that English people, when they realized the needs of the situation, would respond loyally and would render unnecessary the setting up of machinery for compulsory rationing.

CARE OF WOMEN MUNITION WORKERS

Various precautions are being taken by the Ministry of Munitions to maintain health among the women munition workers who are now employed by thousands throughout the country. The hours of labor, though necessarily long, are being steadily reduced, and Sunday labor is being abolished, except when the work is bound to be continuous. In no case may a woman work longer than sixty hours a week, unless a special permit be granted to the employer by the Home Office, after consultation with the Ministry of Munitions. Without such permission, the maximum hours of a woman worker on a twelve hours' shift are ten and a half a day, with seven hours on Saturday, a minimum daily interval of one hour for dinner and half an hour for tea being enforced. The welfare of women in engineering shops is being safeguarded by the Health of Munition Workers' Committee and the Welfare Department of the Ministry. Canteens, cloak rooms and rest rooms are being increasingly introduced into the factories. Seats for the workers, labor-saving applicances and safety equipment in connection with the machinery are being more extensively employed. Welfare supervision in the factory has become a normal feature, and a complete system of housing munition workers in bungalows, hostels or colonies has sprung up.

Sir William Herschel

Sir William Herschel, author of the finger-print identity system, has died. Born in 1833, he was a grandson of the famous astronomer, the discoverer of Uranus, and a son of the no less eminent astronomer and chemist, Sir John Frederick Herschel. He entered the Indian Civil Service in 1859, after the suppression of the mutiny. He applied the first tests of the practicability of using finger-print impressions as means of identification. His object was to circumvent the ersonation then prevalent in the Bengal courts of justice and which, in the general state of illiteracy, could seldom be checked by a comparison of signatures. As early as 1823, Purkenje, the physiologist, had drawn attention to the subject of finger impressions; but it was Herschel, more than a generation later, who proved by practical application their individuality and their persistence for a term of at least fifteen years. His recommendation of their general adoption for civil purposes throughout India was not followed, and the practice lapsed after his departure for other spheres. But his enthusiasm for the system did not abate; and though he evolved it amid "depressing difficulties," he had the satisfaction in later years of seeing his methods applied in all parts of the world on a larger scale than he had ever anticipated. In 1897, nearly twenty years after he had left the country, the government of India accepted the recommendation of an expert committee that finger-prints should be adopted as a means of identification both for civil and for criminal purposes as being in every way superior to the anthropometric method.

PARIS LETTER

Paris, Oct. 25, 1917.

Death of Professor Dastre

French science has sustained a great loss in the person of Professor Dastre, who died as the result of an automobile accident, at the age of 73. He was one of the most noted French physiologists, one who followed in the footsteps of Claude Bernard and Paul Bert, whose student and collaborator he was. [The cable despatch stated that he had been run over by an automobile at the same corner where Professor Curie met with a similar fatal accident a few years ago.]

Jules Albert Franck Dastre was born in Paris, Nov. 7, 1844. He was a student at the Superior Normal School, then a Fellow of physical science, licentiate of mathematical science, doctor of natural science, and then he entered on the study of medicine, presenting his doctorate thesis on "Diabetic Asphyxia" in 1879. From 1872 to 1876 he was laboratory assistant of Claude Bernard at the College of France, and of Paul Bert at the Museum of Natural History. He was appointed supplementary professor of physiology at the Faculté des Sciences in 1876, and in 1887 he was made full professor. In 1904, he was made a member of the Académie des sciences, and in 1908 of the Académie de médecine.

DASTRE'S WORK

Dastre's researches in physiology were conducted on various phases of this science. Particularly worthy of note are his researches on the composition of birds' eggs and their value as nutriment to the embryo; on the storing up of fats, their digestion, their origin and their utilization in the organism; the rôle played by the starches and various sugars in nutrition. He thus cleared away many obscurities in the phenomena of nutrition, specifying the rôle played by fat bodies in these processes and the production of fat bodies by various digestive glands. In the domain of the nervous system he demonstrated the general existence, in all the organs, of inhibiting nerves which oppose the exciting action of other nerves. His studies on the physiology of the heart added to our knowledge of the causes of the rhythm of the heart beat, and his researches on the liver threw new light on the multiplicity of functions of that organ, notably in the production of fats and in the storing up of the iron necessary for the formation of red blood cells. Some of the more important of his works are the following: "Experimental Researches on the Vasomotor Nervous System" (1884), in collaboration with J. P. Morat; "Anesthetics: Physiology and Surgical Application" (1890); "Researches on the Coloring Matter of the Liver and of the Bile and on Liver Iron" (1898), in collaboration with N. Floresco; "Life and Death" (1903). He also was a collaborator on the staff of the French *Scientific Review*, *Philosophic Review* and the *Review of Two Worlds.*

The War

TREATMENT OF WOUNDS OF THE SOFT PARTS

At a recent session of the Société de chirurgie de Paris, Dr. P. Duval, professor agrégé at the Faculté de médecine de Paris and surgeon of the hospitals, presented a very interesting communication on the results he has obtained in the army, thanks to a new special organization, created at his instigation, for the distribution, evacuation and treatment of soldiers sustaining wounds of the soft parts, the most numerous of all. Treated under the best conditions they heal quickly and well; treated under less favorable conditions, they may be followed by the worst complications. The fundamental principle, which, apparently, is accepted by every one today, is that all wounds of the soft parts should be treated within the period of the first twelve hours by opening up the wound widely and removing all foreign bodies. The surgical wound left can then be treated either by immediate suture or by secondary suture done after progressive sterilization. The immediate suture is beyond question the method of choice, but it can be carried out only under fixed conditions: experienced surgeons, perfect equipment, and every possibility of a hospital residence of at least fifteen days with the operating surgeon. For the last reason, primary suture may be made the rule during quiescent periods, but would be the exception during periods of activity when the majority of the wounds of the soft parts can get only secondary suture.

DEFERRED PRIMARY SUTURE

In order to remedy this state of affairs, as far as possible, Duval has adopted the following organization: Behind the evacuating centers, but as near to them as the commandant will permit, large surgical formations, with numerous operating rooms, are established, to be used solely for the treatment of wounds of the soft parts. Two such formations, accommodating many hundreds of wounded, are designated to receive soldiers who are to be treated by primary suture. The other surgical formations are to take care of such wounded as have been sent from the evacuation hospital, but they must send them on to the rear as quickly as possible, in from eight to twelve hours after the primary treatment. Instructions are given to these surgical groups to treat these wounds as follows: Lay them wide open, excising all dead tissue, removing foreign bodies, and then applying simple aseptic dressings after ether lavage. The evacuation of the wounded so treated is finally made to a designated center in the rear where, at the proper time, secondary suture is performed.

RESULTS

By reason of the perfect teamwork done by the surgical formations at the front and those farther inland, the most remarkable results have been obtained, as is shown by the following data: About one third of these wounded were sent to the two centers provided for treatment by immediate suture. Of this number, 67.5 per cent. were treated by primary suture, with only 4 per cent. of failures. Not a single grave accident was noted. Two thirds of the wounded were operated on in the special formations reserved for the treatment of these wounds in the manner outlined above, that is, without suture. Not a single accident was noted. These patients were sent to the base hospitals in less than twelve hours after operation and in less than twenty-four hours after they were wounded. Of those wounded who were operated on in the front line and then evacuated rapidly to the base hospitals, and had their wounds sutured secondarily, 81 per cent. were so treated within eleven days after having been wounded and operated on. No untoward results were noted among this class; no deaths, no gas gangrene, no tetanus, only one case of septic complication—an amputation for arthritis of the knee with purulent discharge, which developed as a late complication of a wound of the foot. Fully 84 per cent. of the wounded evacuated were sutured and cured completely within five weeks after they were wounded.

One sees that it is hardly necessary to regret that immediate primary suture, which is the method of choice, cannot be applied to all the wounded during an offensive movement. The retarded primary suture, that is, suture done after several days, yields equally good results as immediate primary suture. The systematic progressive sterilization of surgical wounds is therefore a method which is useless in about two thirds of the cases, and the secondary suture should give way to deferred primary suture. The latter has further the following advantages: simplification of the treatment, a notable reduction in the length of the treatment, and lastly—

to which too much attention cannot be drawn—a more complete cure. The primary delayed suture, when made in healthy tissues, restores these tissues to almost perfect function. The cicatrix is soft, flexible and nonadherent.

Motherhood Welfare Work in Factories

The manufacturers who employ, for purposes of national defense, a large number of female workers are taking steps to insure the protection of motherhood. They are creating many associations formed for the purpose of providing various measures needed for the protection of these women. One of these associations, the Maternité ouvrière de Levallois-Perret et de Neuilly, has built, on a large piece of ground in close proximity to several large factories, where hundreds of women are employed, a model motherhood welfare institution, which was opened by M. Loucheur, minister of munitions, MM. Albert Thomas and Paul Strauss. In this institution are provided all of the hygienic and comfort measures demanded by the Committee on Women's Work appointed by the minister of munitions. On the occasion of this dedication, M. Loucheur declared himself to be in perfect accord with his predecessor, M. Albert Thomas, in regard to the welfare work among workers, especially the protection of the health of female workers. He has given freely of his counsel for the development and perpetuity of this effort, as outlined by the originators of this movement.

Discontinuation of the Meatless Days

The régime of the meatless days is coming to an end. The results of the inquiry made by the minister of agriculture as to the supply of grazing live stock (*cheptel*) on July 1, 1917, which was published in the *Journal Officiel*, permitted of taking count up to a certain point of the consequences resulting from the institution of meatless days. The total figures for each kind of stock are: horses, 2,282,560 head; cattle, 12,443,304 head; sheep, 10,586,594 head. Comparing these figures with those given Dec. 31, 1916, it will be noted that since that time the live stock has been augmented by about 36,000 head of horses and about 100,000 head of cattle, although the number of sheep has diminished about 250,000 head and pigs about 160,000 head. It was mainly an insufficient supply of potatoes which was responsible for the reduction in the raising of pigs, and therefore the steady increase in price. This year, however, the potato harvest has been most abundant, and there is reason therefore to count on larger numbers of hogs being raised.

Marriages

Lieut. Ambler Baxter Patton, M. R. C., U. S. Army, Great Falls, Mont., to Miss Ruth Wells, of Athens, Ga., at Charlotte, N. C., October 21.

Charles G. Morgan, M.D., to Miss Garnett German, both of Moundsville, W. Va., at Fairmont, W. Va., October 4.

Guy H. Wilson, M.D., Bicknell, Ind., to Miss Maude Ecker of Collinsville, Ill., at Bicknell, November 1.

Julius Mordecai Rosenthal, M.D., to Miss Renée Prisament, both of Monticello, N. Y., October 6.

Frank Walter Hannum, M.D., Muskegon, Mich., to Miss Lynne Carr of Rhinelander, Wis., October 17.

Irving Hotchkiss Pardee, M.D., to Miss Margaret E. Trevor, both of New York City, October 27.

Daniel T. Sullivan, M.D., Mansfield, Mass., to Miss Helen M. Leonard of Brockton, Mass., October 30.

Eugene Emmett Birmingham, M.D., to Miss Theresa Celia Kelly, both of Chicago, October 24.

Lemuel Harris Kerr, M.D., Louisville, Ky., to Miss Marie Chenoweth, at Cincinnati, November 1.

Gundmund J. Gislason, M.D., to Miss Esther Thorgrimsen, both of Grand Forks, N. D., October 24.

Sterling Price Bond, M.D., Little Rock, Ark., to Miss Mary Kitchens of Denver, October 24.

John Carl Wahl, M.D., Scranton, Pa., to Miss Ethel Somers of Philadelphia, October 25.

Stanley Brady, M.D., to Mrs. Lillian London, both of New York City, October 24.

George Arthur Bemis, M.D., to Miss Ruth Lewis, both of Garner, Iowa, October 31.

Deaths

Charles Henry Stanley Davis, M.D., Meriden, Conn.; New York University, New York, 1866; aged 77; clerk of the Meriden City Medical Association since 1870; representative to the state legislature in 1873, and 1885-1886; mayor of Meriden in 1887-1888, and city treasurer, 1898-1899; physician to the State School for Boys from 1895 to 1900; physician to the Curtis Home for Old Ladies and Orphans from 1886 to 1906; trustee, secretary and treasurer of the State School for Boys for four years, and president of the Meriden Board of Education for six years; well known as an archeologist; editor of *Biblia,* a journal of oriental archeology, since 1887; and associate editor of the *American Antiquarian and Oriental Journal,* since 1906; author of many books on science and archeology; died in the Middletown State Hospital, November 7.

Margaret Abigail Cleaves, M.D., Yonkers, N. Y.; State University of Iowa, Iowa City, 1873; aged 69; a Fellow of the American Medical Association; formerly assistant physician at the State Hospital for the Insane, Mount Pleasant, Iowa; and physician in charge of the female department of the State Hospital for the Insane, Harrisburg, Pa.; founder and director of the New York Electro-Therapeutic Clinic Laboratory and Dispensary; author of "Light Energy: Its Physics, Physiological Action and Therapeutic Application"; died in a hospital in Mobile, Ala., November 14.

W. Godfrey Hunter, M.D., Louisville, Ky.; Miami Medical College, Cincinnati, 1871; aged 76; a surgeon in the Federal service throughout the Civil War; a member of Congress from the third and eleventh districts of Pennsylvania; United States minister to Guatemala during President McKinley's administration; died in the Deaconess Hospital, Louisville, November 2, from hemorrhage of the kidney.

Frederick Boty Elliott, M.D., Pittsburgh; West Pennsylvania Medical College, Pittsburgh, 1896; aged 45; formerly a Fellow of the American Medical Association; local surgeon to the Pittsburgh and Lake Erie and Baltimore and Ohio railroads; at one time a member of the local school board; a member of the staff of the Allegheny General Hospital; died at his home, November 4, from heart disease.

Lewis Arthur Welles Alleman, M.D., Geneva, N. Y.; Jefferson Medical College, 1886; aged 55; formerly a Fellow of the American Medical Association; a member of the Medical Society of the State of New York; formerly professor of diseases of the eye in Long Island College Hospital, Brooklyn; died at his home, November 3.

Jacob Maurice Morin, M.D., Brockton, Mass.; Long Island College Hospital, 1899; aged 48; a Fellow of the American Medical Association, and once president of the Brockton Medical Association; a member of the surgical staff of the Brockton Hospital; died at his home, September 12, from chronic interstitial nephritis.

Thomas Maher Reade, M.D., Springfield, Ohio; Washington University, St. Louis, 1871; aged 67; a member of the Ohio State Medical Association; and for a number of years a member of the board of trustees of the Springfield City Hospital; died in that institution, October 31, from cerebral hemorrhage.

Estella Horton Houghton, M.D., Chicago; Northwestern University Woman's Medical School, Chicago, 1899; aged 54; formerly a member of the Illinois State Medical Society; a specialist on diseases of the eye, ear, nose and throat; died in Wesley Hospital, Chicago, October 24, from cerebral embolism.

William Shannon Pollard, M.D., Evansville, Ind.; Miami Medical College, Cincinnati, 1871; aged 79; a veteran of the Civil War; formerly a member of the Indiana State Medical Association, and a member of the staff of Deaconess Hospital, Evansville; died in a hospital in that city, November 1.

Harry A. Nickerson, M.D., Camden, Del.; National Normal University, Lebanon, Ohio, 1890; Medico-Chirurgical College of Philadelphia, 1899; aged 50; formerly a Fellow of the American Medical Association; a member of the Delaware State Medical Society; died at his home, November 4.

Marshall Curtis Munn, M.D., Sycamore, Ill.; College of Medicine and Surgery, Physio-Medical, Chicago, 1893; Hospital College of Medicine, Louisville, Ky., 1895; aged 58; a member of the Illinois State Medical Society; died at his home, October 15, from tuberculosis of the larynx.

Acting Asst.-Surg. Ward Boleyn MacCaffry, U. S. P. H. S., Fortress Monroe, Va.; Medico-Chirurgical College of Philadelphia, 1906; aged 42; for many years in charge of the Cape Charles Quarantine Station; died in Philadelphia, November 4, from a general nervous breakdown.

Emmet Lincoln Smith, M.D., Bellefontaine, Ohio; Chicago Homeopathic Medical College, 1888; College of Physicians and Surgeons, Chicago, 1893; aged 52; for many years a practitioner of Zanesfield, Ohio; died at his home, November 3, from cerebral hemorrhage.

T. R. League, M.D., Greenville, S. C.; Medical College of Georgia, Augusta, 1868; aged 71; formerly a member of the South Carolina Medical Association; at one time a member of the house of representatives from Greenville County; died at his home, October 31.

Ralph E. Gustin, M.D., Detroit; Hahnemann Medical College, Chicago, 1881; aged 67; who was recently sentenced to imprisonment for one to fifteen years for performing an illegal operation; died in the hospital of the state penitentiary, Jackson, November 7.

Lieut. John Charles Murphy, M. R. C., U. S. Army, Hinesburg, Vt.; University of Vermont, Burlington, 1905; aged 35; formerly a member of the Vermont State Medical Society; died in Fort Ethan Allen, Vt., July 19, from purpura hemorrhagica.

Fielding Lewis Davis, M.D., Evansville, Ind.; Homeopathic Hospital College, Cleveland, 1870; aged 86; formerly a Fellow of the American Medical Association, and said to have been the oldest practitioner of Evansville; died at his home, November 1.

Homer Abraham Borin, M.D., Haw Knob, Tenn.; Lincoln Memorial University, Knoxville, Tenn., 1914; aged 33; physician for the Tellico River Lumber Company; was shot and instantly killed near Tellico Plains, November 4, by a young farmer.

George Murphy, M.D., Fort Wayne, Ind.; University of Wooster, Cleveland, 1870; aged 79; a veteran of the Civil War; formerly lecturer on chemistry and toxicology in the Fort Wayne Medical College; died at his home, November 3.

Basil M. Woolley, M.D., Atlanta, Ga.; Atlanta, Ga., Medical College, 1882; aged 82; a Confederate veteran; who was struck by an automobile, October 26; died from his injuries in the Davis-Fischer Sanitarium, Atlanta, November 28.

Arthur Martin Clapp, M.D., Springfield, Mass.; Harvard Medical School, 1902; aged 41; a Fellow of the American Medical Association; while testing a high-powered electrical coil in his office, October 31, was electrocuted.

William H. Webb, Adams, Ind. (license, Indiana, 1897); aged 91; a practitioner since 1866; and for fifty-six years of that time a resident of Adams; died at the home of his son at that place, November 8, from senile debility.

Mary J. Green, M.D., Philadelphia; Woman's Medical College of Pennsylvania, Philadelphia, 1878; aged 76; a member of the Medical Society of the State of Pennsylvania; died at her home in West Philadelphia, November 3.

Alvin H. Keller, M.D., Sioux Falls, S. D.; University of Nebraska, Lincoln, 1883; aged 64; a graduate of the Philadelphia College of Pharmacy, in 1886; died at his home, November 13, from chronic nephritis.

Jasper N. Tabler, M.D., Atlanta, Ga.; Medical College of Virginia, Richmond, 1869; aged 75; formerly a Fellow of the American Medical Association; died at the home of his daughter in Philadelphia, October 29.

Harry Lorenzo Chapin, M.D., Cleveland; Western Reserve University, Cleveland, 1893; was attacked by an unknown assailant in a hotel in Cleveland, November 8, and died shortly afterward from his injuries.

Carl Fulda, M.D., Brooklyn, N. Y.; College of Physicians and Surgeons in the City of New York, 1901; aged 38; attending surgeon to the German Hospital, Brooklyn, N. Y.; died at Pepperell, Mass., November 8.

James Taylor, M.D., East Liverpool, Ohio; Medico-Chirurgical College of Philadelphia, 1894; aged 46; first city clerk of Johnstown, Pa.; died at his home, November 6, from cerebral hemorrhage.

George W. N. Custis, M.D., Washington, D. C.; George Washington University, Washington, D. C., 1887; Hahnemann Medical College, Philadelphia, 1888; aged 87; died at his home, October 29.

Herschel J. Zeis, M.D., Kenton, Ohio; Starling Medical College, Columbus, Ohio, 1905; aged 36; a member of the Ohio State Medical Association; died at his home, October 31, from diabetes.

William Henry Spilman, M.D., Schoolfield, Ky.; Miami Medical College, Cincinnati, 1869; aged 77; died in the Campbell County Infirmary, Newport, Ky., October 8, from arteriosclerosis.

Charles Edward Stuart Taylor, M.D., Guthrie, Okla.; University of Toronto, Ont., 1874; aged 65; for nearly a quarter of a century a druggist of Guthrie; died at his home, November 1.

John Francis Mumford, M.D., Newtown, Conn.; College of Physicians and Surgeons, Baltimore, 1913; aged 26; died at the home of his parents in Raynham Center, Mass., about October 10.

Edward L. Stahl, M.D., Chicago; Rush Medical College, 1883; aged 64; also a graduate of the Chicago College of Pharmacy; died at his home, November 12, from cerebral hemorrhage.

Alexander T. Stevenson, M.D., Bay City, Mich.; Miami Medical College, Cincinnati, 1891; aged 56; died in Ann Arbor, Mich., July 13, from chronic interstitial nephritis.

Sloan F. Hall, M.D., Orlando, Fla.; University of Nashville, Tenn.; aged 84; for many years a practitioner of Nashville; died at his home, August 26, from uremia.

Oliver R. Diehl, M.D., Bryn Athyn, Pa.; Harvard Medical School, 1915; aged 27; died at his home, July 14, from endocarditis following a streptococcus infection.

Robert S. Stahle, M.D., New Market, Pa.; University of Maryland, Baltimore, 1882; aged 59; died at his home, November 2, from disease of the liver.

John H. Wade, Lesley, Ark. (license, Eclectic State Medical Board of Arkansas, 1903); aged 71; a Confederate veteran; died at his home, October 29.

George Wilbur Tucker, M.D., Wilmington, Ohio; Miami Medical College, Cincinnati, 1879; aged 66; died at his home, October 31, from arteriosclerosis.

John Wesley Story, Jr., M.D., Baker, Mont.; University of Louisville, Ky., 1912; aged 30; died in Miles City, Mont., November 5, from pneumonia.

Samuel H. Riley, M.D., Hudson, Mich.; Eclectic Medical Institute, Cincinnati, 1868; aged 72; died at his home, November 1, from pneumonia.

Thomas S. Motter, Dayton, Ind. (license, Indiana, 1897); aged 80; a surgeon of volunteers during the Civil War; died at his home, November 13.

Martha A. Stevens, M.D., Downers Grove, Ill.; New York Hygeio-Therapeutic College, New York, 1861; aged 82; died at her home, November 2.

Jack R. Sharman, M.D., Meridian, Miss.; Louisville, Ky., Medical College, 1876; aged 66; died at his home, September 4, from arteriosclerosis.

Edward H. Jones, M.D., Arlington, Texas; Tulane University, New Orleans, 1882; aged 61; died at his home, July 9, from bronchiectasis.

Wilson J. Orr, M.D., Springdale, Pa.; Jefferson Medical College, 1873; aged 85; died at his home, November 4, from senile debility.

Herman Meyer, Chicago (license, years of practice, Illinois, 1878); aged 69; died at his home, November 3, from strangulated hernia.

Benjamin F. Felix, M.D., Cerulean, Ky.; Eclectic Medical Institute, Cincinnati, 1886; aged 72; died at his home, October 25.

Edgar DeWitt Hurtt, M.D., Piscataway, Md.; University of Maryland, Baltimore, 1854; aged 87; died at his home, October 28.

Dudley W. Welch, M.D., Parkersburg, W. Va.; Medical College of Ohio, Cincinnati, 1896; aged 45; died at his home, October 30.

James Ward Vance, M.D., Madison, Wis.; Pulte Medical College, Cincinnati, 1881; aged 85; died at his home, October 31.

John H. Agee, Lafollette, Tenn. (license, Tennessee, 1889); aged 67; died at his home, August 17, from cerebral hemorrhage.

Martha J. Creighton, M.D., Chicago; Hahnemann Medical College, Chicago, 1884; aged 84; died at her home, November 14.

Adna Balche Jones, M.D., Wakeeney, Kan.; Rush Medical College, 1882; aged 60; died in Kansas City, Mo., October 27.

The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY, TOGETHER WITH OTHER MATTER TENDING TO AID INTELLIGENT PRESCRIBING AND TO OPPOSE MEDICAL FRAUD ON THE PUBLIC AND ON THE PROFESSION

NOSTRUMS IN RETROSPECT

A Review of Worthless or Unscientific Proprietary Mixtures Previously Criticized

[FOREWORD.—It is over twelve years since the Council on Pharmacy and Chemistry of the American Medical Association was created. Since then there have been but few issues of THE JOURNAL that have not called the attention of the medical profession to the debasing influence on scientific medicine of unscientific or worthless proprietary mixtures advertised to physicians for their use in prescribing. The Council on Pharmacy and Chemistry has investigated and shown many of these preparations to be fraudulent in one way or another, and these reports have been published in THE JOURNAL. In spite of this, these preparations have been advertised continuously to physicians, through medical journals and otherwise, and prescribed by a large number of physicians. One reason for this is that there are many physicians who have never seen these reports—who were not in active practice at the time, or who were not reading THE JOURNAL. We probably have among our readers at the present time 35,000 or 40,000 physicians who were not among the readers of THE JOURNAL twelve years ago. It is desirable, then, that we should take up, in more or less detail, several of the more widely advertised products that have been the subjects of previous reports. It has been repeatedly stated in THE JOURNAL that many of the proprietary mixtures—the so-called ethical proprietaries advertised to physicians—were no better and no worse than "patent medicines" advertised to the public.

Every physician who has the welfare of medicine at heart should put these questions squarely to himself if he has not already taken a firm stand on this whole problem: What is my attitude toward the work of the Council? Are its reports worthy of acceptance? Am I upholding the Council in its efforts to place therapeutics on a rational basis, not by blind faith alone, but by an honestly critical attitude toward it? Am I following the path of indolence by taking the advice of nostrum makers without any serious effort to determine whether they are true or false? In a word, am I really practicing medicine, or am I an unpaid agent and a dupe of nostrum makers? There are other revolutions than political. The public can be wronged just as certainly by the abuse of its confidence in clinicians as by the usurpers of political power, and when the public is thoroughly aroused the heavy hand of retribution is not likely to be too discriminating. That the sins of clinicians are standing out plain for any one who wishes to read is becoming more and more evident. There is but one short and ugly word that properly characterizes the physician who accepts a fee for prescribing that about which he has no more knowledge than has the one for whom he prescribes it. Are you with the nostrum makers or decent medicine?

The article below is the first of a series written for THE JOURNAL by one who is thoroughly conversant with the work of the Council on Pharmacy and Chemistry and can speak authoritatively on questions dealing with the action of drugs and the treatment of diseases. We believe that these articles will prove of interest and profit and that they will help physicians to answer the questions just propounded.]

[ARTICLE I]

BELL-ANS (PA-PAY-ANS BELL)

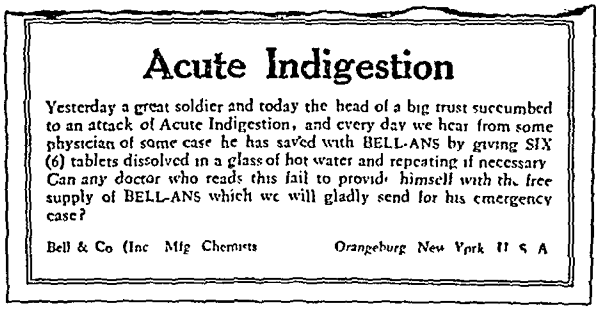
By S. Q. Lapius, M.D.

Bell-ans, for years advertised only in medical journals under the name "Pa-pay-ans (Bell)," is now advertised in newspapers as a remedy that "Absolutely Removes Indigestion." As it is still being advertised to physicians we propose to analyze the claims made for it with as much care as would be exercised in the discussion of the newest discovery in medicine, because we believe that it is desirable to show the trend of exploitation of a certain type of preparation in the medical press.

In the *New York Medical Journal* the following advertisement recently appeared on the front cover:

> ACUTE INDIGESTION
>
> Yesterday a great soldier and today the head of a big trust succumbed to an attack of Acute Indigestion; and every day we hear from some physician of some case he has saved with BELL-ANS by giving SIX (6) tablets *dissolved in a glass of hot water and repeating if necessary.* Can any doctor who reads this fail to provide himself with the free supply of BELL-ANS which we gladly send for his emergency case?

A recently purchased package of Bell-ans contained a circular in which it was stated that Bell-ans removes flatulence, vertigo, weakness and other symptoms of indigestion quickly and pleasantly; that it aids the digestion of food and tends to restore the digestive tract to a normal condition; that it relieves vomiting in pregnancy, alcoholism, seasickness and cholera morbus, besides being pleasant, harmless and effective for colic, sour stomach, feverishness, and wakefulness of infants and children. The circular contained paragraphs purporting to be taken from various medical journals, including the *New York Medical Journal, Wisconsin Medical Recorder,* the *Lancet Clinic, International Journal of Surgery,* and *Massachusetts Medical Journal.* No exact references were given to permit verification or to determine whether or not the quotations were from "reading notices" (advertisements) or from the scientific part of the journals in question. To quote one of the statements given:



Acute Indigestion

Yesterday a great soldier and today the head of a big trust succumbed to an attack of Acute Indigestion, and every day we hear from some physician of some case he has saved with BELL-ANS by giving SIX (6) tablets dissolved in a glass of hot water and repeating if necessary Can any doctor who reads this fail to provide himself with the free supply of BELL-ANS which we will gladly send for his emergency case?

Bell & Co (Inc Mfg Chemists Orangeburg New York U S A

Typical of Bell-ans advertisements as appearing in medical journals.

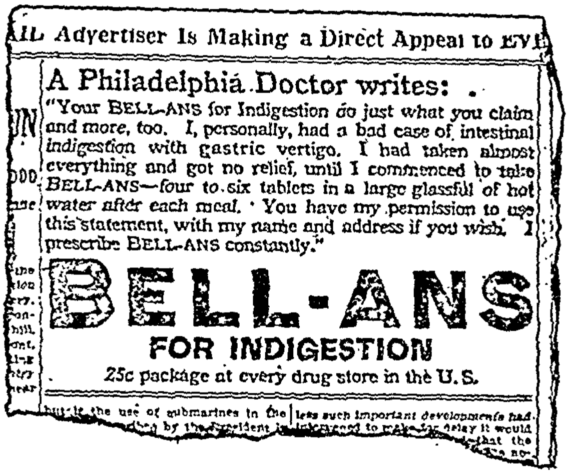
> "The results from the use of Bell-ans (Pa-Pay-ans Bell) in the treatment of indigestion are so prompt and so generally good—and the evidence of this fact is accumulating so rapidly and from such reliable sources—that we venture to suggest to our readers who have not tried this remedy that they prescribe one original sealed package of Bell-ans (Pa-pay-ans Bell) and that they carefully note the results from its use."
>
> "We suggest an original sealed package because the preparation is widely and badly imitated, and unless such a package is specified an imitation of little value may be substituted and the experiment be thus rendered useless."

It is possible that Bell-ans has been imitated, but it is not true that it is widely imitated, for no such imitation has ever been called to our attention, and we strongly suspect that the main reason for desiring that an original package be dispensed is that the patient may see for himself the name BELL-ANS plainly blown in the glass.

The circular in question states that there is no derangement of the digestive organs on which the proper dose of Bell-ans will not act quickly and pleasantly! These are samples of the claims made for Bell-ans. Let us inquire into the nature of the conditions for which the preparation is recommended and the treatment advised by well known clinicians.

The subject of indigestion is discussed by Robert Hutchison and Robert Saundby under the general title of dyspepsia in the "Index of Treatment by Various Writers," Edition 6, 1912, pp. 260-265. Hutchison says: "In the first place it must be remembered that in many patients who complain of 'indigestion' the seat of the trouble is not in the stomach at all."

The general principles to be observed in the treatment of functional dyspepsia, as given by Hutchison, are: (1) To remove the cause; (2) to adapt the diet to the impaired functional power of the stomach; (3) to administer such drugs as are calculated to stimulate or correct the particular function or functions which happen to be impaired, or disordered. Proper diet, proper mastication of food, hygiene of the mouth, and constipation are enumerated as deserving attention. Careful attention to securing a proper diet is essential. The choice of drugs depends, of course, on the conditions that give rise to indigestion, and he calls attention to the necessity of avoiding all routine treatment and compiling one's prescription with an eye to the special disorder or disorders of function, whether secretory, motor or sensory, believed to be present. Hutchison gives the following typical prescriptions to illustrate the use of drugs in the different disorders of function:



Advertiser Is Making a Direct Appeal to

A Philadelphia Doctor writes:

"Your BELL-ANS for Indigestion do just what you claim and more, too. I, personally, had a bad case of intestinal indigestion with gastric vertigo. I had taken almost everything and got no relief, until I commenced to take BELL-ANS—four to six tablets in a large glassful of hot water after each meal. You have my permission to use this statement, with my name and address if you wish. I prescribe BELL-ANS constantly."

BELL-ANS

FOR INDIGESTION

25c package at every drug store in the U.S.

Newspaper advertisement of Bell-ans, capitalizing the statements of physicians.

FOR HYPERSECRETION (HYPERCHLORHYDRIA, ACID DYSPEPSIA, ETC.)

Sodium bromid	10 grains
Bismuth subcarbonate	15 grains
Chloroform water	½ ounce

This mixture to be taken before meals.

Sodium bicarbonate.
Bismuth subcarbonate.
Heavy magnesium carbonate, of each equal parts.

A small teaspoonful of the powder to be taken mixed with a little water or milk about two hours after meals.

FOR DEFICIENT SECRETION (HYPOCHYLIA, ACHYLIA, GASTRITIS, ETC.)

Sodium bicarbonate	10 grains
Tincture of nux vomica	10 minims
Spirit of chloroform	8 minims
Compound infusion of gentian	½ ounce

This mixture to be taken before meals.

Dilute hydrochloric acid and glycerin, of each 15 minims with enough water to make half an ounce, to be taken about twenty minutes after meals.

FOR DEFECTIVE MOTILITY (ATONIC DYSPEPSIA, GASTROPTOSIS, ETC.)

Hutchison recommends the use of 10 minims of tincture of nux vomica in an aromatic vehicle, such as infusion of quassia and compound tincture of cardamom; but another aromatic bitter, such as the compound tincture of gentian, will serve quite as well, of course. This is to be taken before each meal, and for the flatulence that often accompanies this trouble he gives menthol, aromatic spirit of ammonia and spirit of chloroform, as may be needed.

FOR ACID DYSPEPSIA

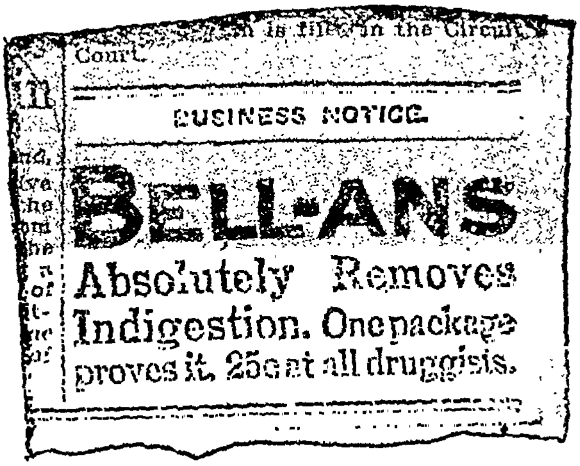
Robert Saundby recommends the following to be used before each meal for the relief of acid dyspepsia: sodium bicarbonate, bismuth subcarbonate, magnesium carbonate, of each 10 grains; mucilage of tragacanth 15 minims, and enough peppermint water to make an ounce.

These are only a few of the conditions that are discussed by Hutchison and Saundby, but they serve to show that the treatment of indigestion by a single prescription or combination is wholly irrational.

Bell-ans, both under its present name and under its older name, "Pa-pay-ans (Bell)," has always been alleged by its manufacturers to contain papain or to be a preparation of the digestive juice from the fruit of *Carica papaya* (papaw) with other substances. Various chemists have attempted to find papain present and to determine the digestive power of the tablets, but without success. For this reason THE JOURNAL suggested that the change of name from "Pa-pay-ans (Bell)" to "Bell-ans" was probably not made entirely for euphonious reasons, as alleged, especially when one considers that the name of a nostrum is its most valuable asset. It is much more likely that as analyses indicated there was not and probably never had been any papain present in the product, the name was changed for fear that some day the misleading term "Pa-pay-ans" might bring the preparation in conflict with the federal Food and Drugs Act.

Pa-pay-ans (Bell) was examined for the Council on Pharmacy and Chemistry in 1909 and the tablets were found to consist of charcoal, sodium bicarbonate, ginger, saccharin and oil of gaultheria. No digestive ferment could be detected in the tablets. Sodium bicarbonate is antacid and serves to dissolve mucus; ginger, if in sufficient amount, causes the expulsion of flatus, and charcoal, while an absorbent in the dry state, is probably useless for any therapeutic purpose whatever after it becomes saturated with gastric juice. Bell-ans, then, has all of the virtues, which are few, and all of the limitations, which are many, of a tablet of sodium bicarbonate and ginger. Its value in the treatment of acute indigestion would be limited to the value of a tablet of such a composition. It is absurd to suppose that it could have the slightest value in the far more serious conditions attended with intestinal indigestion, with the toxemia and autointoxication to which they give rise.

Bell-ans is now advertised directly to the public—but it is no less valuable on that account. True, it is a "patent medicine" in the commonly accepted sense of the term, but it is no more a "patent medicine" today than it was fifteen years ago when it reached the public, not through the direct medium of the newspapers but by the more indirect route of the medical journals and undiscriminating physicians. It is true that, in view of the serious nature of many conditions which are loosely spoken of by the public as "indigestion," its present method of exploitation is likely to make it just that much more dangerous because of the larger publicity that will be given. The point to be borne in mind is that Bell-ans is now in fact what it has always been in essence, a "patent medicine."



is filed in the Circuit Court.

BUSINESS NOTICE.

BELL-ANS

Absolutely Removes Indigestion. One package proves it. 25c at all druggists.

Typical of Bell-ans advertisements as appearing in newspapers.

Again we ask the question: How do you wish to be classified, Doctor—among those who follow blindly the lead of a firm of nostrum makers, or among the intelligent members of the profession who study their cases carefully and prescribe intelligently? The manufacturers of Bell-ans claim that 100,000 American physicians now prescribe Bell-ans, and that 600,000,000 of the tablets are sold annually. If this is even approximately true it is a serious reflection on the medical profession, for the Council examined Bell-ans and reported its findings nearly eight years ago (THE JOURNAL A. M. A., Aug. 14, 1909), and the statements made in that report are as incontrovertible today as they were then.

Correspondence

DECENCY AND SAFETY AS PUBLIC HEALTH FACTORS

To the Editor:—Forcing the nation at large, by public health legislation, to adopt the idle fancies of the rich is advocated, at least by implication, in Dr. North's "Decency and Safety as Public Health Factors" (The Journal, Oct. 13, 1917, p. 1214). He proposes that "esthetic" requirements should be introduced into public health laws, and decries the "pragmatists" and "realists" who will not put into force any compulsory requirements beyond those definitely proved to be real requisites to safety. So direct a challenge to the best trend in modern public health thought certainly deserves a reply.

We are but struggling now from the slough of "esthetic" requirements, serving no useful purpose, which the old public health presented, and your author would have us return thereto. The amount of money spent in the past fifty years, even to this day, on "esthetic" measures would have placed us, had it been properly expended to diminish disease and death, fifty years in advance of where we are now. Nothing makes public health legislation more farcical, or gains for it more bitter and deserved opposition, than the belief, right or wrong, once established in the public mind, that the measures advocated are unnecessary, or based on a fad. Yet your author actually advocates fads as a useful guide to such legislation. The one great virtue of modern public health is that it goes to the nation for recognition and support on the real merits of its measures as proved life savers and life prolongers—that it disclaims all other objects, and refuses to be muddled with them; and this one great virtue he would have us lose!

Moreover, Dr. North misses the main point of estheticism, i. e., that it is a matter of taste and training. His crowning fallacy is that such happiness or enjoyment as "esthetics" gives can be compelled by legislation. All history shows that the mass of the world prefers liberty to the "enjoyment" he advocates. The war proves this in its every detail, if proof were needed. To legislate compulsory safety is the supreme duty of every government. To legislate compulsory happiness, which always means happiness of the brand enjoyed by the legislator who at the time is legislating, would be pure Prussianism—the essence of the evils which precipitated the war.

To make a legal requirement just, it must be applicable to all citizens equally. Hence, whatever advice may be given to the citizen, compulsion of the citizen can be justified only on incontrovertible evidence of its value to all, not to a few. Presenting to the ordinary citizen for his selection both silk and cotton underclothing, "esthetics" would I presume at once point to the former. Now suppose every citizen were compelled to buy the cotton. Would not that be an outrage, if he desired silk and had the price? How much more an outrage to compel the citizen to buy the silk, especially if he had not the price. Remember that 90 per cent. of our population are too poor to afford their children even a partial high school education. Remember that 95 per cent. of our population rank no higher in financial status than that of overseers or foremen of factories, and at least 90 per cent. rank below that financial status.

To examine Dr. North's own illustration of praiseworthy "esthetics" in public health, let us consider his "business man of New York" who demands a bottled spring water because of an "esthetic" dislike to the New York City supply on the ground that it has been polluted, although it is now made safe by artificial means.

Let us lay aside the point made by the Massachusetts State Board of Health that the bottled spring waters of that state were often far more impure than the city supplies. Let us ignore the fact that, this being true, such waters were bought on prejudice and ignorance and sold through reliance on false "esthetics," fostered by tradesmen for commercial purposes. Let us suppose that the particular spring water under consideration was, as Dr. North assumes, indeed "pure." Would he then compel the 90 per cent. of the population, unable to send their children to high school from sheer lack of cash, to buy this spring water because it was admired by the "esthetic" sense (?) of the business man, in preference to the wholesome if unsentimental water of New York City? After, mind you, that 90 per cent. have paid already for the wholesome water, in labor and in taxes? Reverse the compulsion and see what an outcry there would be among the business men if they were compelled to drink one water although ready and able to buy the other.

But do not the "esthetics" really run the other way? The spring water itself was without doubt polluted once, and, then (perhaps) was purified (uncertainly, if at all) by Nature's crude filtration. The esthetics that would prefer this (supposedly) more remote pollution, and the (presumably) sufficient purification following, to the definite and definitely known purification of a good city supply is an "esthetics" too tenuous for me to grasp.

Who shall decide what is "esthetics"? I have known people of culture and refinement to revolt shuddering at the cremation of the dead because it was "unesthetic." Is, then, the slow, slimy corruption of the loved one in a moldy grave the "esthetic" demand with which we must all comply? In this dilemma, which would Dr. North "compel" by legislation? I for one would never compel either against the absurdest sentiments of any one, because there is no more safety in the one than in the other; and if greater happiness or content is the portion of those whose loved ones are disposed of in this way or that, why tear such comfort from them, since both methods are harmless?

Again, are not the "esthetics" of pasteurized milk the other way about also? What kind of esthetics is that which revolts at raw meat but advocates raw milk? However, the whole point in pasteurizing milk is to make it safe for those who cannot pay, no matter how they may wish it, the 20 cents or more per quart necessary to insure a raw milk fit for use.

Too long has mankind fought, prisoned and burned his brother to force his own fancies as the brother's law. Though the proposition be made softly and under guise of such good words as "decency" and "purity" (just as those earlier propaganda were carried out under the guise of religion and of civilization), no follower of public health as it has evolved throughout the last quarter century can possibly endorse returning it to the pit from which it has been dug with so much sweat and labor. If we must have "esthetics," by all means have a board of esthetics to legislate it through, but do not burden public health with it, for public health has serious work to do and neither men nor time nor funds for fancies, usually foolish and often definitely harmful, if not in themselves, then in distracting attention, energy and enterprise from the things that really matter.

H. W. Hill, M.D., D.P.H., London, Canada.
Director, Institute of Public Health.

OINTMENTS OF IODIN

To the Editor:—A manufacturer of certain ointments of iodin brought to me a few months ago some of his preparations and asked me to have them chemically examined. This request was granted and the examinations were made by competent chemists who ascertained that the composition of the ointments was practically in agreement with the claims of the manufacturer.

There was no statement concerning the medicinal value of these ointments. The manufacturer has seen fit to use my report as an advertisement of the medicinal value of his preparations. I am willing to assist him in his endeavor and am ready freely to express my opinion concerning the value of these preparations.

In the first place, the preparations of this manufacturer are in no way superior to preparations which any competent registered pharmacist might make.

In the second place, in my opinion, ointments containing iodin have but little medicinal value. This is not a proper form in which to apply iodin in order to get its local action.

V. C. Vaughan, M.D., Ann Arbor, Mich.

REQUEST FOR REPRINTS ON CANCER

To the Editor:—Dr. Angelo Roffo, Saenz Pena 719, Buenos Aires, Argentina, is desirous of obtaining reprints of American literature dealing with experimental and clinical problems concerning cancer. Dr. Roffo is a member of the medical faculty of the University of Buenos Aires, the leader in that country in the study of cancer problems and the representative of the faculty in the new institute now being built for the experimental and clinical study of cancer. Dr. Roffo would appreciate receiving reprints from American writers interested in cancer, and not only would file this literature for the use of workers in the cancer laboratory and hospital but also would abstract it for the Argentine medical weeklies. I am sure he would appreciate any assistance our workers might give him in this connection.

Richard M. Pearce, M.D., Philadelphia.

SIGNS OF FRENCH MAPS AND HIGHWAYS

To the Editor:—Some of the signs used on French maps are unfamiliar to Americans, even though accustomed to reading our own maps. Likewise the highways of France have indexes and warnings, the meaning of which must be understood to be useful to the traveler. Many American officers and soldiers will be traveling in France in the near future, and, in the hope of being useful to them I enclose sketches showing a few of the most ordinary abbreviations, markings and signs which I have found convenient to know in going about the country.

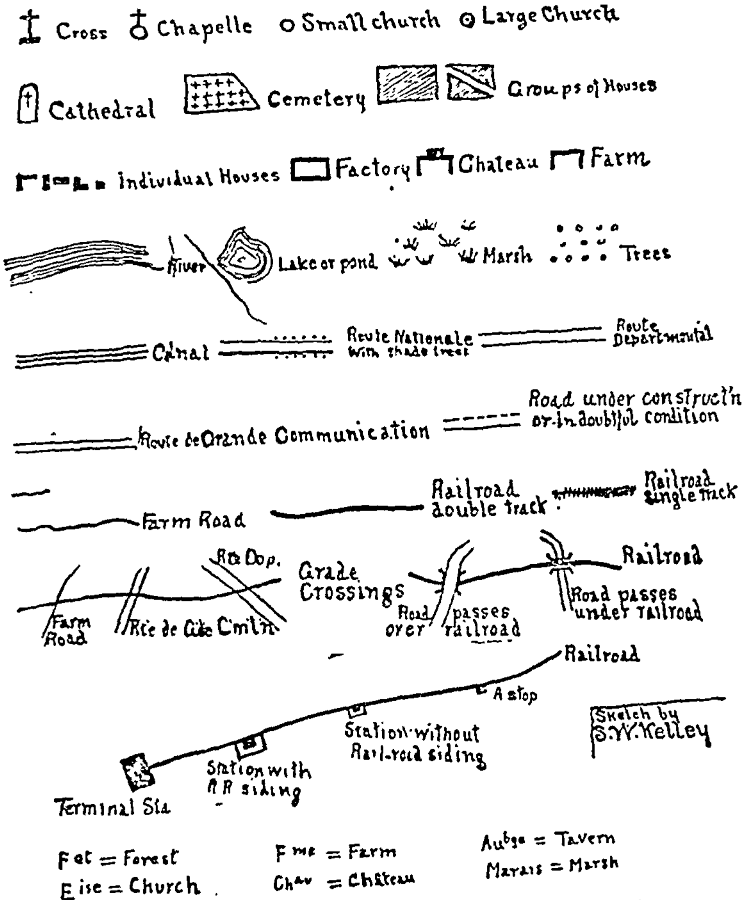


Fig. 1.—Markings and abbreviations in use on French maps.

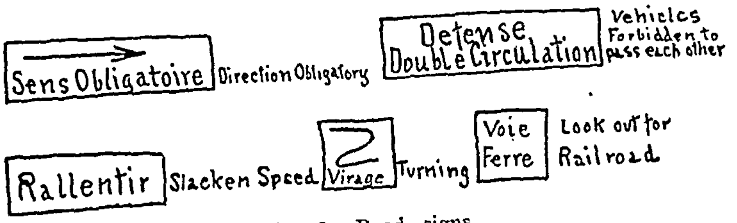

Fig. 2.—Road signs.

Samuel W. Kelley, M.D., Cleveland.
Secteur Postal 205, France.
Chirurgien, Ambulance des Alliés.

BARBARITIES IN MEXICO

To the Editor:—An interesting side-light on the barbarities practiced by the soldiery of Zapata is shown by a patient who a short time ago entered the United States Marine Hospital here suffering from acute gonorrhea. On examination it was found that the penis had been amputated about one-half inch back of the corona. The patient stated that last year he was a soldier in the Carranzista army, and in a skirmish with some of Zapata's men he was captured and severely tortured. He was told that he was to be castrated and made to eat his testicles. They finally compromised by offering him death by hanging, with the alternative of having his penis amputated. He chose amputation. The penis was amputated with a saber. He was left to his fate, but happily was picked up by an ambulance driver, who stopped the flow of blood with a bandage.

The patient further stated that he knows of men who have had their ears, nose, tongue and penis amputated by Zapata's men and Villa's men, and portions of these parts forced down the victims' throats.

The stump had evidently received some surgical attention, as the skin of the shaft had been drawn over the raw surface, completely covering it. In the center of the stump was the small orifice of the urethra. The patient stated that erections are less frequent than before the amputation, and the sexual desire is less. He experiences, however, very little difficulty in performing coitus, and has ejaculations. On admission he had a very active acute gonorrhea with an epididymitis.

R. B. Acker, M.D., New Orleans.
Assistant Surgeon, U. S. P. H. S.

THE HANDICAP OF PROPRIETORSHIP IN MEDICINE

To the Editor:—I am enclosing a reprint of my article on the "Present Status of Pituitary Extract in Labor," which appeared in The Journal, June 2, 1917, p. 1601, and also the September issue of Parke, Davis and Company's *Therapeutic Notes,* on page 89 of which they quote this article, that you may compare the two. The *Therapeutic Notes* article is ostensibly a copy, but as a matter of fact, it gives it only in part, which seems to me to be a gross misrepresentation, and one which I do not think should go unnoticed.

Joseph J. Mundell, M.D., Anacostia, D. C.

[Comment.—*Therapeutic Notes* is one of the house organs of Parke, Davis and Company. A part of each issue is usually devoted to "excerpts" from current literature. The *Therapeutic Notes* may be judged from the manner of "excerpting" the article of Dr. Mundell. Naturally the interest of Parke, Davis and Company is in those sections of the article which may be expected to promote the use of Parke, Davis and Company's proprietary preparation of pituitary extract—pituitrin. The following passages from the article of Dr. Mundell were not among those "excerpted" in *Therapeutic Notes:*

"Used here in properly selected cases, after due consideration by one who has good obstetric judgment, its results are usually happy, and it is a boon to the tired mother and her attendants."

"To step beyond these narrow confines of indications is indeed entering on dangerous territory. Especially is this true as regards the life of the baby. It is recommended in small doses by some good authorities and is frequently used in cases of slight contraction at the brim with sometimes very good results if the birth occurs within a few minutes, but frequently with disastrous results to the baby if delivery is delayed. In such cases, forceps are urgently indicated. Its use in such cases is risky beyond question. Pituitary extract is recommended in cases of postpartum hemorrhage, but ergot is undoubtedly to be preferred."

"All means should be exhausted to arrive at a definite diagnosis, and the dangers of its use should be fully appreciated and due consideration given before its administration in any case, for such a powerful drug, used indiscriminately, will surely produce sad results to mother or child or both."

"During the past two years a number of untoward effects and consequences of severe character have arisen. As far as the maternal accidents and complications are concerned, I firmly believe that were the slogan of the hour "safety first" borne in mind, a number of them could have been prevented, for beyond question this drug has been greatly abused, as it has been given in too large doses, in cases in which its use was strongly contraindicated, and often, I am sorry to say, for no reason other than the accoucheur's expediency. Its use has been reckless and careless. The many reports of its rapid and safe action

> have been one of the greatest dangers. DeLee says, 'It provides for the physician and his brother gynecologist a lot of chronic sufferers, often incurable, even after mutilating operations.' "
>
> "An analysis of the detailed reports of all these cases of ruptured uterus with one or two exceptions reveals the fact that pituitary extract was abused, being given to patients who should not have had it. To my mind, to give a dose of pituitary extract to a woman who has a contracted pelvis, mild or severe, when the head has not passed through the pelvis, is criminal and, if the obstetrician is not aware of the contraction, he is still little short of being a criminal."

In the latter part of his article in The Journal, Dr. Mundell analyzes the reports of twelve cases of rupture of the uterus, thirty-four cases of fetal deaths, and forty-one cases of asphyxia pallida in which "resuscitation was effected only after prolonged and vigorous efforts." These also were not excerpted.—Ed.]

THE ETIOLOGY AND DEVELOPMENT OF NEPHRITIS

To the Editor:—My attention has been called to the fact that in my article on this subject (The Journal, Oct. 13, 1917, p. 1223), I overlooked important experimental work which was done by Prof. Oskar Klotz of Pittsburgh and published in the *Transactions* of the Association of American Physicians in 1914.

I regret this oversight because Professor Klotz' experiments were conducted in much the same way as our own, and because in some respects he seems to have had even more conclusive results than we obtained. Professor Klotz at that time (1914) already noticed the characteristic lesions in the glomeruli produced by intravenous injections of streptococci, and he seems to have been more successful than we in obtaining, in addition, characteristic lesions in the interstitial tissue.

I hope that you will publish this letter so as to give proper credit to Professor Klotz' work in this connection.

William Ophüls, M.D., San Francisco.
Executive Head, Division of Pathology, Leland Stanford Junior University School of Medicine.

EXPEDIENT FOR RELIEVING SITUATION ARISING FROM SHORTENING OF INTERNSHIPS TO ONE YEAR

To the Editor:—At a conference of representatives of leading hospitals of this city, called recently by the Public Health Committee of the Academy of Medicine, it was ascertained that a number of hospitals, for the purpose of accommodating themselves to the program of the Medical Department of the Army, have, with some reluctance, shortened the period of their internships to one year.

All of those present at the conference agreed that an intern period of one year is insufficient for adequate clinical training.

I believe that the general adoption of an intern service of one year, especially at this time, when a large proportion of the members of visiting staffs of hospitals are being withdrawn for military service, thus increasing the responsibilities of interns, will seriously impair hospital efficiency and will react unfavorably on medical standards in the Army and in the community at large.

I quite appreciate the difficulty of relieving the situation through special legislation or by any radical change in the Surgeon-General's regulations, which now grant permission to commissioned interns to remain on the inactive list for the completion of one year of hospital service. However, a means is available of safeguarding the interests of hospitals, and indirectly of serving the public, without a radical change by, or serious embarrassment to, the Medical Department of the Army.

The expedient which I would suggest is the very simple and practical one of a change in the wording of the Surgeon-General's "Circular of Information on the Completion of Internships of Commissioned Officers" (Form I-1), permitting the period of internship "so far as the Surgeon-General's Office is concerned" to terminate in December of the year following graduation, instead of in July of that year; permission to remain on the inactive list for the period named would, of course, be granted only "if the exigencies of the service permit."

S. S. Goldwater, M.D., New York.
Chairman, Committee on Hospital and Medical Facilities.

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

CATHETERIZATION OF INFANTS

To the Editor:—I was recently treating a child—a girl 1 year old—from whom I wished to obtain a sample of urine. I suggested using a catheter, but the parents had been told by a "children's specialist" that a catheter should never be used on an infant; that it was an extremely dangerous procedure and apt to cause inflammation of the bladder from which the child would never recover. Later I heard from the mother, who had taken the baby to a children's hospital, that the house physician had told her that he had never catheterized a baby and never would. I looked the matter up in several books and have asked a number of physicians their opinion; but so far I have not been able to get any satisfactory information. I do not see why using a catheter on an infant should be an operation attended with any particular danger if aseptic precautions are taken. If it is dangerous, I am unable to understand why it is not so mentioned in our textbooks. I shall appreciate an answer to this question or an opinion from you on the subject. If it is not a rational procedure to catheterize a child, I believe you will be doing a service to many members of our profession by publishing this letter and your answer. If you do this, please omit my name and address. W. C. J.

Answer.—There is no reason to believe that catheterization of female infants is any more dangerous than the catheterization of older persons. Not only is the procedure a permissible one, but it is highly advisable when there is difficulty in obtaining urine, and especially in cases in which pyelocystitis is suspected. The procedure is absolutely necessary, if one wishes to find out the nature of the infecting organism in a case of pyelocystitis, which must be done if we are to treat the patient intelligently. It should be stated here that pyelocystitis is a frequent infection in children, and would be diagnosed often if catheterization were done in cases in which the cause of the rise of temperature is in doubt.

SALVARSAN

To the Editor:—At a recent meeting of a clinical club in this city, the fact developed that men thoroughly conversant with the use of arsenical preparations (salvarsan, etc.) could give us no definite information as to which of the American and Canadian products now on the market are most reliable both as to therapeutic results and absence of toxicity.

It seems well that a statement on this matter should be made by the Council on Pharmacy and Chemistry if it is possessed of that information; and if not, that it should at once take steps to come to a decision and relieve the profession of the uncertainty of the situation.

I shall be pleased if it is possible for you to give me an answer as to which preparation I ought to use.

J. E. Tuckerman, M.D., Cleveland.

Answer.—In addition to the German made salvarsan and neosalvarsan, now practically off the market, the Council on Pharmacy and Chemistry has admitted to New and Nonofficial Remedies diarsenol, manufactured by the Synthetic Drug Company of Toronto, Canada, and arsenobenzol made by the Dermatological Research Laboratories, as products essentially the equal of salvarsan. It has also accepted *neodiarsenol*, manufactured by the Synthetic Drug Company, as essentially equivalent to neosalvarsan. The Council has under consideration at the present time salvarsan manufactured by the Farbwerke-Hoechst Company, New York.

Before accepting these preparations, the Council required evidence to show that the products are manufactured under supervision which may be expected to insure its chemical identity and uniformity and its freedom from toxicity. It should be remembered, however, that, in the past untoward effects have been reported from German salvarsan and neosalvarsan possibly due to idiosyncrasy, but more probably to the fact that certain lots (probably through some faulty technic in the manufacture) were more toxic than others. This has been the case particularly in regard to the last shipments of neosalvarsan from Germany. Recently some untoward effects from neodiarsenol have also been reported. No conclusive evidence is available, we believe, that shows difference in the toxicity or therapeutic efficacy between the German made salvarsan, diarsenol or arsenobenzol (Dermatological Research Laboratories); though reports have been received that the last product, while somewhat less soluble than salvarsan, is more nearly free from toxic action than salvarsan.

We are informed that within a short time all salvarsan, neosalvarsan and the various products identical with these will be tested by the government before their sale is permitted. This control is to be established by the Federal Trade Commission under the authority of the recently passed "Trading with the Enemy Act." This act, among other things, provides for the manufacture of synthetics covered by German patents under licenses issued by the Federal Trade Commission. Such licenses, we are informed, will provide for government control of each lot manufactured, and may also stipulate the maximum selling price.

DEATH RATE FROM TUBERCULOSIS—DISEASES WITH GREATEST MORTALITY

To the Editor:—1. How many people die annually of tuberculosis in the United States? 2. What is the percentage per thousand? 3. What is the average age of those who die of this disease? 4. In their order of mortality, what diseases occupy first, second, third, fourth and fifth places?

J. E. Brinkman, M.D., Waterloo, Iowa.

Answer.—1. According to the mortality statistics of the Department of the Bureau of the Census for 1915, tuberculosis of different parts of the body caused 98,194 deaths during 1915, which is 10.8 per cent. of the mortality charged to all causes for that year.

2. All forms, 145.8 per hundred thousand; tuberculosis of the lungs, 127.7 per hundred thousand.

3. The average age of those who die of pulmonary tuberculosis is about 35 years.

4. The death rate during 1915 per hundred thousand population was as follows:

Organic heart diseases	156.2
Tuberculosis (all forms)	145.8
Pneumonia (all forms)	132.7
Nephritis	104.7
Cancer	81.1
Cerebral hemorrhage	79.3

SOLDIERS' AND SAILORS' INSURANCE LAW

To the Editor:—I notice an editorial in The Journal of November 17 about the Soldiers' Insurance Law. This article states that the insurance should be applied for within 120 days. As I am on the reserve list, I would like to know whether this means 120 days after receipt of commission, or after receiving orders for duty. Please give me information about this law, or tell me where to find such information.

Milton J. Stern, M.D., Paris, Ky.

Answer.—Members of the Medical Reserve Corps not on active duty are not entitled to insurance either under the automatic provisions of the law or on application. The language of the Act (Sec. 401) relating to the time for applying for the insurance is: "Such insurance must be applied for within 120 days after enlistment or after entrance into or employment in the *active service* and before discharging or resignation, except that those persons who are in the active war service at the time of the application (Oct. 15, 1917) of the terms and conditions of such contract of insurance may apply at any time within 120 days thereafter and while in such service."

Medicine in Recent Fiction.—Voivenel remarks in a recent issue of *Progrès Médical* that medicine, and especially objective psychology, seems to be regarded by the writers of the day as worth flirting with. But our science is a princess who has more malice and wit than she seems to have. She likes to render ridiculous those who would flirt with her. But she is gracious to the writers who take the pains to deal seriously with her.

Medical Education and State Boards of Registration

COMING EXAMINATIONS

Colorado: Denver, Jan. 8. Sec., Dr. David A. Strickler, 612 Empire Bldg., Denver.

Delaware: Wilmington, Dec. 11-13. Sec., Dr. H. W. Briggs, 1026 Jackson St., Wilmington.

District of Columbia: Washington, Jan. 8. Sec., Dr. Edgar P. Copeland, The Rockingham, Washington.

Florida: Jacksonville, Dec. 4-5. Sec., Dr. W. M. Rowlett, Citizens Bank Bldg., Tampa.

Hawaii: Honolulu, Jan. 10-13. Sec., Dr. G. A. Batten, Box 375, Honolulu.

Indiana: Indianapolis, Jan. 8-10. Sec., Dr. Wm. T. Gott, 84 State House, Indianapolis.

Kentucky: Louisville, Dec. 4-6. Sec., Dr. A. T. McCormack, Bowling Green.

Louisiana: New Orleans, Dec. 6-8. Sec. Pro-tem., Dr. E. W. Mahler, 730 Audubon Bldg., New Orleans.

Maryland: Baltimore, Dec. 11. Sec., Dr. J. McP. Scott, 137 W. Washington St., Hagerstown.

Minnesota: St. Paul, Jan. 2-4. Sec., Dr. Thomas McDavitt, 741 Lowry Bldg., St. Paul.

Missouri: St. Louis, Dec. 17-19. Sec., Dr. George H. Jones, 206 Washington St., Jefferson City.

National Board of Medical Examiners: New York City, Jan. 9-17. Sec., Dr. J. S. Rodman, 310 Real Estate Bldg., Broad and Chestnut Sts., Philadelphia.

New Hampshire: Concord, Dec. 10-12. Sec., Dr. W. T. Crosby, Beacon Bldg., Manchester.

North Dakota: Grand Forks, Jan. 1. Sec., Dr. G. M. Williamson, Grand Forks.

Ohio: Columbus, Dec. 4-6. Sec. Pro-tem., Dr. Herbert M. Platter, 185 E. State St., Columbus.

Oklahoma: Oklahoma City, Jan. 8-9. Sec., Dr. J. J. Williams, Weatherford.

Oregon: Portland, Jan. 1. Sec., Dr. Herbert S. Nichols, Portland.

Pennsylvania: Philadelphia, Jan. 8-10. Sec., Nathan C. Schaeffer, State Capitol, Harrisburg.

Rhode Island: Providence, Jan. 3. Sec., Dr. B. U. Richards, State House, Providence.

South Dakota: Pierre, Jan. 8. Sec., Dr. P. B. Jenkins, Waubay.

Utah: Salt Lake City, Jan. 7-8. Cor. Sec., Dr. G. F. Harding, 407 Templeton Bldg., Salt Lake City.

Virginia: Richmond, Dec. 11-14. Sec., Dr. J. W. Preston, McBain Bldg., Roanoke.

Colorado January Examination

Dr. David A. Strickler, secretary of the Colorado State Board of Medical Examiners, reports the written examination held at Denver, Jan. 2, 1917. The examination covered 8 subjects and included 80 questions. The percentage required to pass was 75. Nine candidates were examined, of whom 8 passed and 1 failed. One hundred and fifteen candidates were licensed through reciprocity, including 99 osteopaths. The following colleges were represented:

College	Year Grad.	Per Cent.
PASSED		
University of Colorado	(1915)	77.3
Chicago College of Medicine and Surgery	(1916)	89.3
Hering Medical College	(1895)	80
Harvard University	(1914)	84.4
Jefferson Medical College of Philadelphia	(1910)	81.2
Lincoln Memorial University	(1915)	78.2
Baylor University	(1913)	86.5
University of Toronto	(1907)	85
FAILED		
St. Louis College of Physicians and Surgeons	(1915)	70

College	Year Grad.	Reciprocity with
LICENSED THROUGH RECIPROCITY

Albany Medical College	(1901)	New York
Meharry Medical College	(1905)	Alabama
Vanderbilt University	(1912)	Tennessee
Memphis Hospital Medical College	(1886)*	Arkansas

*Official information on file indicates that this candidate is not a graduate of the medical school named.

Missouri June Examination

Dr. George H. Jones, secretary of the Missouri State Board of Health, reports the written examination held at St. Louis, June 18-20, 1917. The examination covered 14 subjects and included 100 questions. An average of 75 per cent. was required to pass. Of the 117 candidates examined, 113 passed and 4 failed. Eleven candidates were licensed through reciprocity. The following colleges were represented:

College	Year Grad.	Per Cent.
PASSED		
Chicago College of Medicine and Surgery	(1916)	82.3
University of Illinois	(1916)	87.4
University of Louisville	(1917)	86.9

Book Notices

The Secretion of the Urine. By Arthur R. Cushny, M.A., M.D., LL.D., Professor of Pharmacology, University of London, University College. Cloth. Price, $3 net. Pp. 241, with 36 illustrations. New York: Longmans, Green & Co., 1917.

This presents a critical digest of the entire literature on normal kidney function. The author states that he did not feel able "to adventure on the difficult subject of renal pathology." Hence at the end of the volume only three short chapters are devoted to glycosuria, albuminuria and nephritis. This is to be regretted, since the author's able exposition of normal kidney function would have served as a valuable norm for the interpretation of renal diseases. In the preface, Cushny registers a severe indictment of present day investigators of kidney function. "The growth in the literature on the kidney has been most extraordinary, and this increase in bulk has not gone along with an improvement in quality, but rather the reverse. No other organ of the body has suffered so much from poor work as the kidney, and in no other region of physiology does so much base coin pass as legal tender." This stricture is essentially just, and applies with equal force to the physiologist, the pharmacologist, the pathologist and the clinician. This monograph will help to speed the advent of a new day of greater accuracy and more severe critique in medical research. The book is a useful and opportune contribution to physiology and medicine.

Shell Shock and Its Lessons. By G. Elliot Smith, M.A., M.D., F.R.C.P., Dean of the Faculty of Medicine, University of Manchester, and T. H. Pear, B.Sc., Lecturer in Experimental Psychology, University of Manchester. Cloth. Price, $1 net. Pp. 135. New York: Longmans, Green & Co., 1917.

This is a remarkably fine and most timely little book. Abroad our colleagues are constantly seeing examples of shell shock, and unless present signs fail, many of our medical men, military and civil, are going to see the same thing. A more succinct and reasonable treatment of the subject can scarcely be imagined. Chapters IV and V are devoted to a spirited criticism of the British attitude on insanity and the insane, on neuroses and the neuropaths, are not particularly germane to the title of the book, and are less applicable, we hope, to the United States than to England. But the preceding chapters on shell shock are wholly admirable. Any physician expecting to see such cases should be compelled to read these chapters with care. Before the patient can be shown that he has not a mysterious, unheard of, horrible malady, the physician must be as familiar with this disorder as he is with typhoid. Before the physician can really reach an apparently inaccessible patient, in all reason he should know the reasons of his apparent inaccessibility and the principles of approach. For the attainment of this intimate acquaintance and clarity of vision, the brochure in hand will be of inestimable value. Careful perusal of the three chapters leads one to at least two definite conclusions: Shell shock has brought us no new symptoms. These patients should be handled by experts: by men equipped with the necessary brains, training, experience and proper hospital facilities.

An Epitome of Mental Disorders. A Practical Guide to Aetiology, Diagnosis and Treatment for Practitioners, Asylum, and R. A. M. C. Medical Officers. By E. Fryer Ballard, M.B., B.S., Captain R. A. M. C. (T.). Cloth. Price, $2.25 net. Pp. 211. Philadelphia: P. Blakiston's Son & Co., 1917.

When a person in a foreign country knows nothing of the language, the little books of current phrases in parallel columns are very useful. Being perhaps lost in a tangle of streets, he looks up the equivalent of "Will you kindly direct me to the Grand Hotel?" and has a fair chance of reaching his hostelry. To be sure, he may first find himself at the Grand Central Station, and then maybe at the Grand Emporium of Novelties; but he neither feels nor is so helpless as he would be without his handy volume. Captain Ballard's epitome may be compared with such a little handbook. But we hasten to add that the very first line of the preface states that "this little book is not intended for students of medicine," and the third line informs us that the author "has not aspired to write a textbook of psychiatry." For the kind of book that it does aspire to be, it is excellent. We know of no work that could be so quickly and truly useful to "practitioners" and "assistant medical officers in asylums" ignorant of psychiatry, incompetent to make an accurate diagnosis in mental disorders and to treat the insane. We do not doubt that such a book is needed, will be used, and will be a real help not only in the United Kingdom but also in the United States. That this is true is pathetic. It means that the insane and mentally unbalanced are not getting the service they should have. We should also commend the book to the host of new medical men in the army who, if they see service, are sure to see mental cases with which they are entirely unfamiliar and yet concerning which they will have to make some decision. In this connection we should add that the chapter on shell shock is vague in statement and entirely inadequate: not to be compared with the handling of the subject in the little book of Smith and Pear.

The American Encyclopedia and Dictionary of Ophthalmology. Edited by Casey A. Wood, M.D., C.M., D.C.L., Professor of Ophthalmology and Head of Department, College of Medicine, University of Illinois. Volume 11. Muscles, Ocular to Ophthalmology, History of. Cloth. Price, $6. Chicago: Cleveland Press, 1917.

The first third of the present volume is occupied by the continuation of the article on the ocular muscles, and the latter half by an instructive history of ophthalmology from the earliest times, including a brief account of ophthalmologic associations in America and American ophthalmologic journals. Concerning the character of this great work, it is believed that a judicious and courageous employment of the editorial blue pencil would have improved the historical article. The objection is not to the matter, but to the method of treatment. Other important topics in the volume are myopia, neosalvarsan, nephritis and eye symptoms, neurology of the eye, nystagmus, oblique astigmatism, and ophthalmia neonatorum (not fully treated here). The illustrations are abundant, as usual, and those of the historical article important to have preserved in a work of this sort.

A Text-Book of First Aid and Emergency Treatment. By A. C. Burnham, M.D., Medical Reserve Corps, U. S. Army, Instructor in Surgery in the Polyclinic Hospital, New York City. Cloth. Price, $2. Pp. 307, with 162 illustrations. Philadelphia: Lea & Febiger, 1917.

In this book, first aid methods are concisely and practically treated in a manner well within the comprehension of such groups as boy scout and Red Cross classes, factory foremen, first aid industrial teams, or the troops of the Sanitary Corps. The illustrations are well chosen. Every topic in the brief preliminary chapter on anatomy closes with a practical reference to first aid surgical considerations. The chapter on transportation of the injured, an adaptation of the regulations of the Sanitary Corps of the United States Army, is especially lucid and concise. The work includes a description of first aid treatment of the sick as well as of the injured. The recently perfected mechanical respirators are discussed. This small book is noteworthy throughout for the absence of anything not germane to its purpose of a clear description of first aid methods.

Sanitation for Medical Officers. By Edward B. Vedder, M.D., Lieutenant-Colonel, U. S. Army. Medical War Manual No. 1, Authorized by the Secretary of War and Under the Supervision of the Surgeon-General and the Council of National Defense. Leather. Price, $1.50. Pp. 211, with 24 illustrations. Philadelphia: Lea & Febiger, 1917.

This is one of the manuals authorized by the Secretary of War, and published under the supervision of the Surgeon-General. It is issued as a guide for medical officers in the control of sanitary work. The author claims no originality for the material presented, much of which is compiled from other books on military hygiene and sanitation. Such Army orders as are of special value to medical officers are quoted, and others are mentioned by number so as to enable ready reference by those wishing to go into any subject in greater detail. The volume is interleaved with blank pages for making notes. It is a practical handbook for the purpose for which it was prepared.

Medicolegal

Duty and Liability of Owner or Operator of Sanatorium

(Robertson vs. Charles B. Towns Hospital et al. (N. Y.), 165 N. Y. Supp. 17)

The Supreme Court of New York, Appellate Division, Second Department, says that it is the duty of the owner of a sanatorium conducted for private gain to use reasonable care and diligence, not only in treating, but also in safeguarding, a patient, measured by the capacity of the patient to provide for his own safety. In the discharge of this duty, physicians and nurses possessing that reasonable degree of learning and skill that is ordinarily possessed by persons similarly engaged must be employed, and they must act with reasonable care and diligence. In this case, a patient, who had been advised to go to a sanatorium for treatment for alcoholism, was assigned to a room on the third floor, the one window in which room was guarded with a metallic grating. A few days later a physician and a nurse attached to the hospital found him in the room with an uplifted pitcher in his hand, after he had driven forth his roommate, whom he falsely charged with an attempt to kill him. The physician's attention was attracted to the incident by having heard a sound like "rattling the screen"; that is, the metallic grating on the window. The patient, being persuasively subdued and his fear apparently dispelled, then started for the lavatory, and the female nurse asked the physician to accompany him. The physician was about to do so instantly when he heard a crash. He rushed in. He saw the body of the patient falling through the window, which was of ground opaque glass and was not guarded. He grabbed him, but could not hold him, and he fell to the ground, where he died a few minutes afterward from the injury thus caused. The case was barren of evidence that conscious suicide should have been foreseen. There was, however, evidence that the patient had a delusion that his roommate had a design to kill him, and it was inferable that he shook the window screen in his bedroom in an attempt to escape from his imaginary assailant. There was also evidence that he had alcoholic delusions, and that fear of bodily harm and an impulse to escape an imaginary foe are characteristics of these delusions; and evidence that the delusion may manifest itself, disappear and shortly recur. The court thinks the evidence recited presented a question for the jury as to whether the physician or the nurse should not, in the exercise of the requisite skill and care, have foreseen such a casualty and protected the patient from the unguarded window in the bathroom. But the court holds that a judgment against the hospital and Charles B. Towns, for damages, must be reversed, because, while there was evidence on which the jury might have found either liable, there was no evidence on which they could be held jointly. The physicians and the nurse were not the servants of both. The jury did not decide who was the master. The corporation operated the hospital, or it did not. If it did, it could be liable; if it did not, and the individual defendant was the actual operator and master, why should there be a judgment against it?

Refusing to Submit to Reasonable Treatment —Results as Evidence

(Peterson vs. Branton (Minn.), 162 N. W. R. 895)

The Supreme Court of Minnesota holds, in this action to recover damages for alleged negligent and unskilful treatment of a fracture, that, when a patient refuses to submit to the reasonable treatment prescribed by a surgeon, from that time on the fault is with the patient, and not with the surgeon. And when a patient refuses to submit to the reasonable treatment prescribed by his surgeon, the surgeon may give in evidence his opinion of what the result would have been had the treatment that he prescribed been followed. It is also recalled that this court has held that, in an action against a physician to recover damages for negligent or unskilful treatment of a patient, the result alone is not evidence of negligence; but an expert witness may give his opinion, based on the result, that the treatment must have been improper, and such an opinion is evidence on which the court or jury may find negligence.

The court says that the plaintiff, a man 49 years old, Oct. 25, 1914, sustained a fracture of both bones of the right forearm between 3 and 4 inches from the wrist. The defendant, after describing his treatment, testified that the plaintiff continued to come to his office in the hospital until some time in March, 1915; that up to the time he examined the arm, December 29, it was straight and the bones in perfect alinement; but that when he examined the arm in March he found there was a nonunion of the radius, and the ulna was crooked; that he then informed the plaintiff of the condition and advised him that further methods were necessary, and that he would have to give him another anesthetic and treat the ununited ends of the ulna so that they would unite; and that the plaintiff refused to submit to such treatment. At this stage of the trial the defendant was asked whether, in his judgment, a good arm would have resulted, if the plaintiff had followed his advice. To this an objection was sustained; but the supreme court holds that the testimony sought to be elicited was admissible under the pleadings, and that to exclude it was error.

This was not a personal injury case in which the wrongdoer claimed that the injured party could have reduced his damages by an operation to which he refused to submit. In such a case the injured party is not required to submit to an operation for the benefit of the person who caused the injury. But in this case the defendant contended throughout the trial that the condition of the arm was due to no fault of his. That he properly reduced the fracture in the first instance was conceded by the plaintiff's expert witnesses. The defendant claimed that the failure of union was due either to some act of the plaintiff, or to some cause for which neither party was responsible, a situation which the testimony showed is not unusual in cases of this character. If the defendant's claim of freedom from fault was well founded, a question he had a right to have submitted to the jury, it was his duty, on discovery of the nonunion, to advise the plaintiff of the necessary and proper treatment to be thereafter pursued. Proper advice is part of proper treatment, and if from that time on there was fault in any one, it lay with the plaintiff, and not with the defendant. It was defensive matter going directly to disprove the charge in the complaint, and not in mitigation of damages or to establish contributory negligence. The defendant claimed that in this respect as well as in all others he performed his whole duty toward the plaintiff; and in connection with his advice he had a right to state to the jury his opinion as to the result of the treatment he prescribed had it been followed.

The jury returned a verdict for $4,500 for the plaintiff, from which the trial judge required him to remit $1,500, or to have a new trial granted to the defendant; but, on account of the error in the exclusion of the testimony sought to be elicited by the question to which objection was sustained, the supreme court holds that a new trial should be granted, and reverses the order denying the defendant's motion for one.

Information Derived from and in Presence of Third Persons

(North American Union vs. Oleske (Ind.), 116 N. E. R. 68)

The Appellate Court of Indiana, Division No. 2, says, in this action brought by plaintiff Oleske to recover on a beneficiary certificate for the death of her husband, that the insured on the morning of the day on which he died was suddenly stricken with severe illness, the nature of the ailment being in controversy. The insured was unconscious, and remained in that condition until he died. The plaintiff, discovering his condition, sent for certain neighboring women, and also called a physician. At the trial, the defendant offered to prove by the physician some statement made by the plaintiff to him in the presence of such neighbors and relative to the insured's condition. The statement, if made at all, was made while the physician, assisted by the neighbors and by the plaintiff, was examining the insured with a view to treatment, the insured being at that time unconscious. The testimony was excluded as privileged, which the court holds as right. The insured, being unconscious, was unable to give to the physician any account of the cause, origin, or history of his ailment. It was necessary that such service be performed by another, if at all, and it would seem that the wife should be considered a proper person to give such information. Where the intervention of a third person is necessary in order that the patient may communicate with the physician with a view to intelligent treatment, neither the physicians nor such third person may disclose, over objection, information so communicated. To information obtained by a physician while treating his patient, the privilege may attach, notwithstanding the presence of third persons in the sickroom, where the consultation is held. It is held, however, that disinterested persons present when a patient communicates with his physician relative to the ailments of the former may testify to such communications. The privilege extends not only to communications from the patient to the physician, but to information derived by the physician from persons present at the interview. It is true that the weight which should otherwise be assigned to the New York decisions is detracted from somewhat by the fact that the governing statute of that state is not identical with the Indiana statute. Nevertheless, the court regards the situation presented here as arousing the spirit of the Indiana statute, and as a consequence that the evidence sought by the testimony of the physician was privileged and properly excluded.

MINNESOTA STATE MEDICAL ASSOCIATION

Annual Meeting, held at St. Paul, Oct. 11-12, 1917

The President, DR. HARPER M. WORKMAN, Tracy,
in the Chair

Tumors of the Bladder and Their Nonoperative Treatment

DR. W. F. BRAASCH, Rochester: In summarizing our experiences with the nonoperative treatment of tumors of the bladder, it may be said: 1. In cases of primary tumor, fulguration is applicable only to the papillomatous tumors of a relatively benign type. 2. Although the ultimate results following fulguration are much superior to those following suprapubic resection, the method does not always offer a permanent cure. 3. Recurrence most often takes place within a year following fulguration, and is usually at the site of the primary tumor. 4. Multiple recurrence is more often observed with multiple primary tumors. 5. The interval of recurrence and the evident degree of malignancy are lessened by repeated fulguration.

Cesarean Section

DR. H. T. MCGUIGAN, Red Wing: We have had no maternal mortality in our series, and only one infant mortality, which occurred one week after delivery, from causes in no way incident to the operation. These uniformly good results can be ascribed in a large measure to the fact of having the patients in the hospital and directly under control. unnecessary examinations were not made and the patients were operated on before they had become physically exhausted from long labor pains. It appears to us after our experience with the operation that it is advisable to employ it in many more cases than it is at present. One cannot help being convinced of this by watching a convalescence from a high forceps operation and a cesarean section.

DISCUSSION

Dr. H. B. Sweetser, Minneapolis: In the case of a primipara, with an undilated os, with convulsions, cesarean section seems to be a life-saving measure. About a month ago I saw a woman with a low blood pressure, who had had two convulsions. She seemed to be in a very fair condition, so that I did not advise cesarean section. She was delivered in the afternoon of a small child without any trauma; still she died. Another woman recovered from a cesarean section, and in about a week became maniacal. The condition lasted a few days, and then she recovered.

Dr. Carey Culbertson, Chicago: It has remained for the American obstetrician to emphasize the value of cesarean section for the relative indication, as it is called in the textbooks. By the relative indication we mean all of the other things for which we are now doing cesarean section, instead of the absolutely contracted pelvis. In the clinic of Dr. J. Clarence Webster, I have seen a woman with an acute anemia from placenta praevia develop an infection after a version and extraction, and I have seen a woman who is sectioned as soon as she begins to bleed. Comparing the difference in the recovery, the difference in the fetal mortality, and the difference in the subsequent morbidity, there is no question as to the advantage of cesarean section in a number of these cases.

Focal Infections in the Nose and Throat: Means of Diagnosis and Elimination

Dr. W. E. Patterson, Minneapolis: Focal infections are not wholly confined to the teeth, tonsils and accessory sinuses, but one may find the same constitutional effects resulting from a diseased appendix, or an abscess formation around an ingrowing toenail. As to the relative significance of the various foci in the head, in my opinion the teeth come first, the faucial tonsils second, then the accessory sinuses, and lastly the middle ear and mastoid. I have found vaccines in conjunction with local treatment to be a most valuable aid in many cases. The essentials in the treatment of sinus infections are drainage, and when there is a resultant anemia, some form of tonic treatment.

Effect of Tonsillectomy on Focal Infection

Dr. Norven H. Gillespie, Duluth: Joint, heart, kidney, goiter and glandular conditions show such marked improvement after tonsillectomy as to leave no doubt as to the source of the infection. The infection may be divided into two groups, that due to chronic conditions in the tonsil itself, and that reaching the tonsil from without, through the medium of water, milk and other articles of food.

DISCUSSION

Dr. Frank E. Burch, St. Paul: A wave of conservatism is passing over the profession with reference to the removal of tonsils. Their wholesale removal, especially of juvenile tonsils, is a thing of the past. There has been a lack of discrimination in determining what tonsils should and what tonsils should not be removed.

Dr. Charles M. Spratt, Minneapolis: A diseased tonsil without enlargement should be removed. Any person who has recurring muscular or joint trouble, so-called rheumatism, or arthritis, should have his tonsils removed.

Dr. J. D. Lewis, Minneapolis: It is my belief that tonsillectomies, as usually performed, are complete in only 25 per cent. of the cases. I do not believe that by any blunt or sharp dissection method one is able to escape rupture of the capsule and therefore remove the tonsil completely.

Jejunostomy: Its Indications and Methods

Dr. Charles H. Mayo, Rochester: Jejunostomy in the first loop of the intestine is very important in the maintenance of nutrition. It is used principally for palliation in inoperable diseases, and occasionally as a temporary expedient in benign lesions. When it is made low in the jejunum it is classified with enterostomy for the relief of obstruction in the small intestine. The Witzel method of inserting the tube, and the tube drawn through the punctured opening in the omentum, before it is passed through the abdominal wall, guard the opening against leakage and maintain mobility of the bowel.

Pathology and Treatment of Osteomyelitis

Dr. Alexander R. Colvin, St. Paul: It is sometimes said that if acute osteomyelitis were treated properly, there would not be a chronic stage. This is true only in part, for many cases are so insidious in onset that marked bone changes have occurred before we see them at all, and before the patient has had any symptoms impelling him to seek assistance. It is in these chronic forms that the greatest difficulty in diagnosis occurs because of the tumor-like thickening of the bone, with few symptoms; tumor-like masses of indurated tissues surrounding the bone increase the difficulty. After the removal of the sequestrums, each case demands separate consideration as to the best means of dealing with the resulting cavity. In the young, in whom the osteogenesis is comparatively rapid, the bone wax is especially valuable, if for no other reason than for furnishing a kind of drain; but occasionally when drainage ceases it keeps the cavity filled until such time as osteogenesis has built sufficient new bone to obliterate the cavity from which the wax has gradually been absorbed. In adult bones, in which osteogenesis is slow or it may fail to accomplish the desired result, the plastic use of bone, muscle, fat or skin may be desirable. During the course of the disease, joint contractures are prone to occur, and protective and mechanical treatment to prevent these are of the utmost importance. Where the sequestrum involves a large part of the shaft, fracture of the involucrum may also occur if protection is not sufficient.

DISCUSSION

Dr. James E. Moore, Minneapolis: It is our experience at the University Clinic that many patients with osteomyelitis come in who have not been recognized as such, and often present themselves with a diagnosis of rheumatism. At a very early stage the roentgenogram will not show infection in the medullary cavity of bone, even when there is a pronounced abscess at the end of the diaphysis of the long bone.

Dr. Samuel J. Mixter, Boston: An adult may have a sudden acute bone infection. Nearly the whole shaft of the tibia may be involved, and the man is very sick. An opening into the bone is made, with insufficient drainage. That man can be cured only by amputation of the leg. I have seen these patients die in from three to twenty-four hours after such an operation. Amputation will save them, whereas a conservative operation will kill them.

Colles' Fracture

Dr. Owen W. Parker, Ely: The thing of greatest importance in the treatment of a Colles fracture is to reduce it properly, and the next most important thing is not to abuse the use of splints. The successful treatment of all fractures requires good judgment, common sense, constant attention to details, a knowledge of many methods, and the election of the one which in the individual case will lead to a restoration of the form and function of the injured limb in the shortest possible time with the least danger and inconvenience to the patient.

DISCUSSION

Dr. Alexander R. Colvin, St. Paul: A fracture with a little triangular crack through the base of the ulna, without any displacement, is often mistaken for a simple sprain, and many of these injuries, without deformity, may be mistaken for fractures.

Dr. Archibald MacLaren, St. Paul: Colles' fractures should always be reduced under anesthesia. We should never cover any fracture up so that we cannot see it.

Dr. H. B. Sweetser, Minneapolis: I recall two patients who apparently had entirely recovered; but when they returned there were nonunion and deformity. In both of these cases there was evidence of syphilis. I have not seen any cases of Colles' fractures in a normal person when there was nonunion.

Dr. E. P. Hawkins, Montrose: I must protest against the general statement that unless these fractures are reduced properly they do not remain in position. One cannot always reduce them at once. If one can wait for a week and then put the patient under anesthesia, one can reduce all of them; but there are cases, as I know from personal experience, that cannot be reduced at first.

Dr. Arnold Schwyzer, St. Paul: We should not allow the remarks of Dr. Hawkins to go unchallenged, because the time when we can reduce these fractures is at the start. It is the time when we have no callus formation and no additional swelling, and I do not know of a case that cannot be reduced if one follows the advice of the essayist.

Dr. George Earl, St. Paul: Two months ago, a lineman fell from the top of a pole. Among other injuries that he sustained, the ulna was found protruding, dislocated, with a Colles fracture. It was impossible to put the hand in a straigh position to hold the Colles fracture in place because there was also a dislocation of the ulna; it was completely broken off, but by putting it up at an angle we obtained a satisfactory position.

Dr. Samuel J. Mixter, Boston: One may have a tremendous deformity, yet a perfect functional result. The cosmetic result may be bad, but the hand is just as good as ever.

Bursae

Dr. George Earl, St. Paul: Chronic ailments, especially of the extremities, may be due to inflamed bursae. While trauma was at first thought to be all important, increasing recognition has been given to the rôle of infections and other factors, such as metabolic disturbances. Conservative surgical treatment is often sufficient, but pyogenic infection demands incision.

DISCUSSION

Dr. Earle R. Hare, Minneapolis: Oftentimes the diagnosis of surgical bursae is not made, and patients are allowed to suffer indefinitely when a cure might be effected by proper treatment. The etiology is a bone of contention at the present time. There are those who believe that the etiology lies in trauma, while others believe that it lies in infection. With our advancing knowledge of infection, it is very likely that the cause lies more toward the side of infection than it does toward the side of traumatism. Some years ago I removed with perfect result a pair of prepatellar bursae that measured an inch and a half in diameter, and an inch in thickness, even though there was active suppuration going on in one bursa at the time of its removal.

Dr. Arnold Schwyzer, St. Paul: When we have to operate in these cases, whether there are simply a few small deposits or they are infected, we should remove the bursa as a whole.

Dr. Joseph R. Kuth, Duluth: In the past six or seven months I have seen six or seven cases. The impression I received was that the trouble undoubtedly followed trauma; but whether trauma was the primary or sole cause I am unable to say. These cases were notable for their chronicity.

Dr. Louis Daugherty, St. Paul: I have seen three cases of subdeltoid bursitis. In all there were calcareous deposits. I was impressed with the chronicity of the condition. These patients complained of pain in the shoulder joint which radiated down the arm, and the condition was diagnosed as neuritis.

Dr. H. B. Sweetser, Minneapolis: I had an interesting experience bearing on the diagnosis of bursitis. A woman had several sinuses around the hip joint discharging pus. One man made a diagnosis of tuberculosis of the hip. I thought it was tuberculosis of the spine. Roentgen examination showed nothing wrong with the hip. There was no interference with the motion of the vertebrae. We injected these sinuses with bismuth paste without any result, and then I operated and found that the focus of infection was a bursitis in the gluteus maximus muscle.

Dr. M. S. Henderson, Rochester: When the bursae are excised the entire sac should be taken out. In a large number of cases of bursitis which I have seen, the bursae had merely been incised and the sac had not been dissected out.

Rickets, with Especial Reference to Premature Infants

Dr. E. J. Huenekens, Minneapolis: I have been using tricalcium phosphate and cod liver oil in the treatment of rickets in breast fed infants, both full term and premature, with very good results. In the beginning I had great difficulty in obtaining a smooth and palatable mixture, but finally found that 10 per cent. of tricalcium phosphate (C. P.) in emulsion of cod liver oil (U. S. P.) makes a smooth suspension, which is readily taken by most infants.

3 Intestinal Bacteria in Children. W. W. Ford, K. D. Blackfan and M. D. Batchelor, Baltimore.—p. 354.
4 *Relation of Reaction of Urine to Diet in Infants and Children. C. Torres, Bogota, Columbia, S. A.—p. 365.
5 *Banana as Food for Children. M. C. Pease and A. R. Rose, New York.—p. 379.

1. **Reflexes in Poliomyelitis.**—Regan points out that the most common symptom of poliomyelitis is an alteration in the reflexes accompanying or following a short febrile period. The patellar reflex is most frequently affected owing to the common involvement of that region of the spinal cord which innervates the quadriceps extensor group of muscles. It was altered in various ways in 81 per cent. of 818 cases. Hyperactivity of the knee jerks is usually, if not invariably, the first change to occur in the preparalytic stage. Hyperactivity of the patellar reflex is most frequent in the meningitic and ataxic cases, and in the combined types of the disease in which meningitic symptoms were prominent. Absent or normal response is the rule in purely bulbar cases, except in the very early stages. An exaggerated reflex may be encountered in an atrophied and obviously paralyzed leg. Absence of the knee jerk is most frequently encountered in the myelitic and bulbar types of the malady.

The patellar reflex may remain normal throughout the entire paralytic phase, especially in bulbar and ataxic cases. It is also common in myelitic cases when the paralysis is limited to the upper extremities and trunk. It is scarcely ever encountered where the hydrocephalus is at all marked. The plantar reflexes are exaggerated in the preparalytic stage. The reflex was alterated in 41 per cent. of 643 cases specified in the paralytic stage. An exaggerated response may persist into the paralytic stage, more especially in the meningitic and ataxic classes of cases. A diminished reaction was found most common in the ataxic, the myelitic meningitic, and the purely myelitic forms of the disease. The reflex was absent most frequently in the purely bulbar and in the combined bulbar and myelitic cases. A normal reaction was encountered most often in the ataxic, bulbar myelitic and bulbar meningitic forms of the malady. Often the first sign of improvement in cases with marked paralytic involvement is the gradual reappearance of the reflex. The Babinski phenomenon is relatively rare in poliomyelitis, but it occasionally occurs in the meningitic form of the disease. Its presence in a case in which the diagnosis was doubtful would always be decidedly in favor of tuberculous, and, to a less extent, cerebrospinal meningitis. A true ankle clonus is likewise very rare in contradistinction to the other forms of meningitis. The pupillary reflex is but little altered.

2. **Infantile Scurvy.**—Hess emphasizes the fact that infantile scurvy is an intestinal intoxication or an autointoxication due to the overgrowth of harmful bacteria in the intestine. It is the product of an unbalanced flora which is no longer controlled by a proper dietary. Oliguria is a common symptom of scurvy. The mild therapeutic effect of citric acid may be ascribed partly to its diuretic properties. Orange juice also was found to bring about marked diuresis. One of the striking and important symptoms of scurvy is a susceptibility to infection (furunculosis, nasal diphtheria,

"grip," etc.). Some hemorrhages are due to this secondary infection, and are to be regarded not as scorbutic, but rather as focal complications. Other hemorrhages are truly scorbutic. Scurvy, however, is essentially a disorder characterized by malnutrition and not by hemorrhage, taking months to develop, and, from a clinical point of view, frequently latent or subacute.

4. **Diet and Reaction of Urine in Children.**—Torres points out that the difficulties often encountered in changing the reaction of the urine in children are very much diminished when a suitable diet is prescribed. Diminishing the amount of protein in the diet to 2 gm. and sometimes to 3 gm. per kilogram will often in itself render the urine alkaline without using a drug. In cases in which the amount of protein reaches the lowest physiologic limit without turning the urine alkaline, one may continue to diminish the acidity by adding vegetables to the diet. In older children with whom the food is more varied, one can do much by regulating the diet in accordance with the principles outlined in this article. In cases in which vegetables are used to turn the urine alkaline, one must use, if possible, vegetables in which the amount of protein is smaller in proportion to the salts, like fruits, rice, wheat, etc., rather than those which have a large amount of protein like peas, beans, etc. Vegetables which contain purins, like coffee, tea and cocoa, may increase the acidity, because they may produce uric acid. In cases of infection, especially in infections of the urinary tract, and in cases of starvation, the urine tends to become more acid than in other conditions; therefore it is more difficult to render it alkaline. When drugs are used without the proper diet, the doses necessary to make the urine alkaline are much larger than is ordinarily believed. The action of drugs (either acid or alkaline) is very fleeting; therefore they should be given in large and frequent doses.

5. **Banana as Food.**—Numerous digestion experiments were performed by Pease and Rose to determine the food value of the banana. The results of their experiments show that the banana is a useful fruit that can with profit enter liberally into the child's dietary provided it is fully ripe or well cooked. If eaten baked in the yellow stage of ripeness or if eaten raw when fully ripe, the banana makes a delightful and highly nutritious article of food. Its composition does not warrant the use of the banana as the main component of the child's dietary, but it can compete well with other fruits and is decidedly to be preferred to candies. The nutritional value is relatively high, approximately one calorie per gram of pulp; and its carbohydrates, when it is fully ripe or cooked, are not less assimilable than those of cereals and potatoes. In the raw food the digestibility is directly proportional to the ripeness of the fruit. There is no positive evidence that the banana influenced bowel movements. In the many tests there was no suggestion whatever of any deleterious effect from consuming large amounts of fully ripe bananas. Prolonged use of the underripe fruit, on the other hand, developed undesirable symptoms. The banana ought not to be eaten raw until after the brown spots begin to appear. The brown color of the peel, however, should not be confused with the darkening due to bruises. An injured banana is soon invaded by molds and yeast cells. The banana properly handled and allowed to ripen is a wholesome food, uncontaminated by dirt and pathogenic germs even if purchased from the push cart in the congested streets.

American Review of Tuberculosis, Baltimore

October, I, No. 8

6 *Rôle of Surgery in Treatment of Intestinal Tuberculosis. E. Archibald, Montreal, Canada.—p. 449.
7 *Treatment of Tuberculous Hemoptysis with Thromboplastin and Euglobulin. G. Mannheimer and S. L. Wang.—p. 468.
8 Tuberculosis and Pregnancy. Study of Three Hundred Cases with Review of Literature. S. A. Douglass and J. E. J. Harris, Mount Vernon, Ohio.—p. 478.
9 *Experiments with Tuberculous Sputum Twenty-Two Years Old. N. B. Burns, Boston.—p. 484.
10 Clinical Observations Derived from Examination of Over Three Thousand Chests Checked by Stereoroentgenograms. K. Dunham, Cincinnati.—p. 489.
11 Cone and Collateral Circulation in Pulmonary Tuberculosis. K. Dunham, Cincinnati.—p. 498.

6. **Surgical Treatment of Intestinal Tuberculosis.**—Archibald says when the small bowel alone is involved, there is present constipation, often quite marked and there is no thickening or mass, and in particular no tenderness to palpation localized in the cecal region. When the cecum with or without the ascending colon is involved, and the small bowel is free, there is present diarrhea or alternating constipation and diarrhea, and there is always to be felt a fairly defined thickening, sometimes even a mass, and there is tenderness to palpation in the cecal region. When both small bowel and cecum are involved there is a mixture of the above signs and symptoms. When the transverse and descending colons are diseased in addition, there are very rarely any signs that point to it; these are comparatively silent regions. When the appendix alone is tuberculous, it is not possible before operation to exclude the possibility of disease in the cecum; one can only say that there is disease in that region. Between simple appendicitis and tuberculous disease it is often difficult to make a diagnosis; but it may be said that, where definite thickening of the tissues in the appendix region is felt, without there being an acute inflammatory reaction, and with a history of chronic slight pain and of occasional subacute attacks with persisting soreness, then the condition is much more suspicious of tuberculosis of the appendix, and possibly also of the cecum, than of simple appendicitis. While in the majority of cases of intestinal tuberculosis the lungs are already seriously diseased, and while in such cases the early hopes of bringing about arrest of the pulmonary condition by surgical removal of the diseased bowel have not on the whole been realized, it may still be emphasized that complete relief of bowel misery in these distressing cases may very often be accomplished by a well planned and carefully executed operation. The good cases with but little pulmonary trouble and with eradicable bowel disease may frequently be cured by operation.

7. **Thromboplastin and Euglobulin in Hemoptysis.**—Twenty-three cases with moderate or copious hemorrhages which had a tendency to continue were treated by Mannheimer and Wang. All had definite pulmonary tuberculosis with positive sputum. Other medicinal treatment was omitted for the time being. In the beginning small doses were used, as nothing was known about the effects. They were subsequently increased and also given more frequently. When a hemoptysis recurred in the same individual at a later period different dosages were administered. This refers only to thromboplastin, which was used in 23 instances. In two cases a hemorrhage ceased after the injection of thromboplastin, but recurred subsequently and was not influenced by a repetition or increase of the dose. In all the other cases there was even no apparent benefit. Euglobulin was administered fifteen times. There was no improvement in any case. A few patients showed slight reactions as evidenced by a chill, elevation of temperature and general malaise. One developed a typical serum rash. These reactions were not severe and were of short duration. Altogether the author's results with thromboplastin and euglobulin in the treatment of tuberculous hemoptysis have been negative.

9. **Tuberculous Sputum Twenty-Two Years Old.**—In all the material examined by Burns acid fast organisms resembling tubercle bacilli structurally and in staining qualities were seen to be present. They were more numerous in the dried material in which no other organism could be found. No growth was obtained such as would prove, or even suggest, that these organisms still retained their viability. Innoculation of both culture mediums and guinea-pigs produced only negative results in the attempts to recover living tubercle bacilli from the material examined.

Boston Medical and Surgical Journal

November 1, CLXXVII, No. 18

12 *Use of Normal Blood Serum, Particularly with Reference to Treatment of Wounds. T. Leary, Boston.—p. 611.
13 Preparation of Blood Serum for Use. T. Leary and F. H. Dunbar, Boston.—p. 617.
14 *Anaphylactic Reactions to Normal Serums. T. Leary, F. H. Dunbar and J. W. Watson, Boston.—p. 618.
15 Case of Streptococcus Meningitis Successfully Treated with Normal (Human) Serum. F. P. McCarthy, Boston.—p. 621.

16 *Treatment of Wounds with Normal (Béef) Serum. J. H. Shortell, W. F. Cotting and T. Leary, Boston.—p. 622.
17 Physical Examination of Factory Employees; Two Thousand Consecutive Cases and Defects Found. R. W. Cutler, Worcester.—p. 627.
18 Future of Medicine. C. W. Eliot, Boston.—p. 631.

12. **Normal Blood Serum in Treatment of Wounds.**—Leary is convinced that normal serum may be accepted as a natural physiologic solution, readily miscible with the tissue secretions, and bland in its action, apart from certain toxic and anaphylactic properties, now regarded as useful under proper control; it possesses natural antibacterial properties; it is the storehouse of the specific antibodies; it contains ferments capable of digesting tissue detritus and exhibiting other useful activities; it is employed successfully in controlling hemorrhage other than that form (rhexis) requiring mechanical control; it is fitted to serve as a culture medium for tissue; it is able to excite the protective machinery in a nonspecific manner, useful in therapy; it provokes a desirable leukocytosis, valuable in the treatment of infections.

14. **Anaphylactic Reactions to Normal Serums.**—The clinical application by the authors of beef serum in the treatment of wounds has been followed by no anaphylactic phenomena when the serum has been applied to wound surfaces. In six cases injections of serum were made, either subcutaneously or into the deep tissue. The amount injected was about 15 c.c. In three of these cases chills occurred within two hours of the injection. In only one case was the chill marked, the temperature reaching 103. In no case did a delayed anaphylactic reaction appear.

16. **Wounds Treated with Normal Beef Serum.**—The results obtained by the authors in a variety of cases show that serum will control a septic process, wherever contact is made between the serum dressing and the infected tissue. It is absolutely harmless to normal tissue. As a prophylactic agent in fresh wounds it is of value. Serum is a most marked stimulant of granulations. The authors believe that grafting can and should be practiced earlier following the use of serum than under any other agent. Injections of unheated beef serum are followed by rises in temperature, usually slight, perhaps with chill, but the reactions are short and not severe. Used as a dressing to wounds, no matter how large the surfaces are, it gives rise to no anaphylactic response.

Journal of Cancer Research, Baltimore

October, II, No. 4

19 *Relation of Induced Cancer Immunity to Tissue Growth and Tissue Degeneration. F. D. Bullock and G. L. Rohdenburg, New York.—p. 455.
20 *Splenectomy Exerts No Appreciable Influence on Immunity Against Transplanted Tumors. F. D. Bullock and G. L. Rohdenburg, New York.—p. 465.
21 *Loss of Power to Produce Sarcomatous Transformation in Stroma. W. H. Woglom, New York.—p. 471.

19. **Relation of Induced Cancer Immunity to Tissue Growth.**—It is claimed by Bullock and Rohdenburg that induced immunity to transplanted cancer is not solely due to growth or the metabolites of growth of the immunizing agent, nor is it due to death and degenerative metabolites of the injected material.

20. **Influence of Splenectomy on Immunity Against Tumors.**—Bullock and Rohdenburg found that splenectomy has no effect on the persistence of immunity induced by the receding rat sarcoma 7; neither does it influence the fate of regressive tumors. Splenectomized animals are no more resistant to immunizing agents than are normal animals. Splenectomy neither increases the percentage of takes nor favors the growth of spontaneous tumor grafts.

21. **Sarcomatous Transformation in Stroma.**—A transplantable mouse carcinoma, which exhibited in the first generation the power to cause sarcomatous transformation in its stroma, lost that power after the fourth generation, and has not regained it during three years cultivation. The question is raised by Woglom whether mouse tumors containing keratin may not, perhaps, induce sarcoma development in their stroma more often than other types of carcinoma.

Journal of Cutaneous Diseases, Chicago

October, XXXV, No. 8

22 Erythema Figuratum Perstans; Report of Cases. W. H. Mook, St. Louis.—p. 635.
23 Focal Infection in Etiology of Skin Disease. E. D. Chipman, San Francisco.—p. 646.
24 *Glycerin. D. W. Montgomery, San Francisco.—p. 662.
25 *Relation of Fruit Ingestion to Cutaneous Diseases. A. Davidson, Los Angeles.—p. 665.
26 Lymphadenosis Cutis Universalis, Associated with Generalized Erythrodermia and Atrophy of Skin. F. Wise, New York.—p. 669.

24. **Therapeutic Use of Glycerin.**—Glycerin is freely miscible in all proportions with water and with ordinary alcohol, it mixes well with all the ointment bases, and is an excellent solvent. In prescribing mercuric chlorid for tinea versicolor, by adding glycerin, the skin is kept moist and the medicament is retained. The following prescription is written by Montgomery:

℞	Hydrarg. bichlorid	53
	Glycerin	15
	Spts. vini rect. dil.	240

M. Sig.: Rub in well once a day.

One of the best lotions for roughness of the hands, as in chronic eczema, is composed of caustic potash (KOH), glycerin, alcohol and water:

℞	Potassii Hydroxidi	1.00
	Glycerini	
	Spts. vini rect.	āā 66.00
	Aq. rosae	ad 200.00

M. Sig.: Use on the hands once a day.

Petrolatum is the fatty base usually prescribed in ordering a paste, but glycerin may be employed. Such a prescription would be:

℞	Amyli	
	Zinci oxidi	āā 15.00
	Glycerini	30.00

M. Sig.: Apply by spreading on with the hand.

The zinc oxid glycerin jellies form another set of preparations that, when judiciously employed, give excellent service. A formula that Montgomery has found excellent consists of:

℞	Gelatini	46.00
	Zinc oxid	28.00
	Glycerin	12.00
	Aq. ad.	114.00

Heat the water and dissolve the gelatin in it, and then add the glycerin and the oxid of zinc and stir until cold. This makes 200 gm., a little over 6 ounces, which is a convenient amount to dress a surface equal to that of both legs.

25. **Relation of Fruit Ingestion to Cutaneous Diseases.**—According to Davidson if all fresh fruits were stricken from the dietary, one-third of the sickness incidental to childhood and early life would be eliminated. He says that of all California fruits the orange is the most deleterious. The strawberry outranks it as a cause of urticaria but the orange is more prone to cause the furred tongue, cloyed appetite and general depression, a symptom group that is classed as "biliousness." The evil lies wholly in the pulp or cellulose, the juice is perfectly wholesome. Oranges exhibit their poisonous qualities most intensely when eaten fresh off the tree. When cold stored for a few weeks they lose these poisonous qualities and may then be eaten with impunity. Next in order of unwholesomeness come the peach, apricot, plum and cherry. Pears, apples, grape-fruit and grapes seem to produce no anaphylactic symptoms. Dried fruits such as dates, figs and raisins are valuable foods and have apparently no direct action on the skin. Figs are the only dried fruit that have a noticeable laxative action. In mild cases of constipation two or three figs eaten before retiring produce satisfactory results. The imported fig alone has this quality; California figs, including the fertile seeded varieties, do not seem to have this virtue. Raisins, if freely eaten, may cause an irritative diarrhea and in an unusual way; the skins are somewhat tough and difficult to digest and are prone to adhere by their flattened surfaces to the valvæ conniventes, where they may remain for some time before irritation is produced. The musk melon or canteloupe is apparently harmless, but Davidson does not feel quite sure about the watermelon.

The melons belong to a family of plants that in their wild state are drastic purgatives and in the instances where they disagree, they may have possibly reverted to the family habit. Many people eat all manner of fruit not only with impunity but with pleasure and benefit, as it gives them that feeling of repletion that is essential to mental well being and prevents the excessive use of the ordinary proteins. There is a class of people who have digestions akin to those of the herbivora, who can eat, satisfactorily digest and assimilate all manner of fruits and vegetables, and examination of the stools show that the digestion of the cellular elements is complete. These people have one distinguishing feature: they all show a tendency to constipation and high blood pressure. In practice, then, one may lightly regard the possibility of anaphylaxis in these people. On the other hand, in those who suffer from catarrhal affections of the large bowel (and these affections are very numerous, ranging from mild catarrhal inflammation to membranous colitis) the anaphylactic action of fruits is liable to be very marked. There is, too, the possibility that the frequent association of anaphylaxis and colitis may be due to the parenteric action of the colon bacillus gaining access to the blood through the damaged points in the mucous lining.

Journal of Infectious Diseases, Chicago

November, XXI, No. 5

27 *Etiology of Common Colds. Probable Rôle of Filtrable Virus as Causative Factor; with Experiments on Cultivation of Minute Micro-Organism from Nasal Secretion Filtrates. G. B. Foster, Jr.—p. 451.
28 Hemolysin Production and Acid Production by Streptococci. S. Sekiguchi, Chicago.—p. 475.
29 Some Factors in Swimming Pool Control. W. D. Stovall and M. S. Nichols, Madison, Wis.—p. 484.
30 *Preparation and Method of Using Toxin-Antitoxin Mixtures for Active Immunization Against Diphtheria. A. Zingher, New York.—p. 493.
31 Effect of Anilin in Rabbits. M. W. Brown, Chicago.—p. 497.
32 *Wassermann Reaction with Glycerolated Human Serum More than a Year Old. E. H. Ruediger, Bismarck, N. D.—p. 502.
33 *Rocky Mountain Spotted Fever in California. J. G. Cumming, Berkeley, Calif.—p. 509.
34 *Complement Fixation with Specific Antigen in Acute Poliomyelitis. M. Neustaedter and E. J. Banzhaf.—p. 515.

27. **Etiology of Common Colds.**—From the experimental evidence presented by Foster it seems that the following facts have been established: Common colds of the ordinary type are infectious. It has been demonstrated experimentally that the virus of common colds occurs in the nasal secretions; and that this virus is capable of passing through Berkefeld filters which are impermeable to ordinary bacteria. By the employment of special anaerobic methods the virus of common colds has been cultivated in vitro by Foster, and has proved capable of repeated recultivation in subcultures. Experimental inoculations have demonstrated that Berkefeld N filtrates of subcultures of the virus, in the second generation at least, are infective. A peculiar minute micro-organism has been isolated from cultures made from the filtered nasal secretions in common colds. This micro-organism can be passed through Berkefeld N filters, and has been recultivated from culture-filtrates. Although conclusive proof of its nature has not been adduced, the experiments suggest that the micro-organism described bears a definite relation to the true infective agent. Analysis of the results of Foster's experiments showed that of the ten men inoculated, seven developed clear cut and definite symptoms of acute coryza; two reacted questionably, while one remaining case exhibited no symptoms. The experiments were adequately controlled.

30. **Toxin-Antitoxin Immunization against Diphtheria.**—The indications for active immunization with toxin-antitoxin are divided by Zingher into two groups: (*a*) as a general prophylactic measure, and (*b*) to control outbreaks of diphtheria. It is a safe and convenient rule to follow to immunize with toxin-antitoxin all children below 18 months of age irrespective of the Schick test they may show at the time of immunization. The immunity developing from toxin-antitoxin is slow in appearing, and is, therefore, not a reliable safeguard in hospital wards where children are crowded together, and suffering from various contagious diseases. But in institutions where small outbreaks of diphtheria have occurred, or where diphtheria is more or less constantly present and clinical cases and bacillus carriers steadily appear, Zingher says, the use of antitoxin alone has often been insufficient to stamp out the disease, and the combined application of the Schick test and active immunization with toxin-antitoxin has given most successful and encouraging results.

32. **Wassermann Reaction with Old Glycerolated Human Serum.**—Ruediger has found that pure glycerol is an ideal preservative for human serum intended for the Wassermann reaction. In order to prevent the serum from becoming anticomplementary, it must be heated to about 56 C. for thirty minutes and then be mixed with an equal volume of glycerol. Serum kept for more than a year gave practically the same results as when fresh and without preservative.

33. **Rocky Mountain Spotted Fever.**—The results of animal inoculations in Cumming's cases definitely establish the occurrence of Rocky Mountain spotted fever in California. The occurrence of a case in Ventura County marks that region as a new area of possible prevalence of the disease in California.

34. **Complement Fixation in Acute Poliomyelitis.**—Neustaedter and Banzhaf have obtained a specific antigen for complement fixation in poliomyelitis by digesting poliomyelitic virus with trypsin. A 5 per cent. suspension of brain and cord of monkeys that have died of poliomyelitis is filtered through a Berkefeld or Heim filter, sterile water being used as the menstruum. The trypsin is added in proportion of 1:50 and permitted to act at room temperature for three hours; 0.4 per cent. tricresol is then added to stop further action by the trypsin.

38 Lesions of Frontal Lobe Simulating Cerebellar Involvement, *Differential Diagnosis.* A. Gordon, Philadelphia.—p. 261.

35. **Brain Tumor.**—A woman of 49 had a history of convulsions for twenty-nine years, headaches for two years, and many of the usual localization symptoms of brain tumor for four months before her death. Necropsy showed a tumor which might be classed as a glioma, but which Bond says should be considered as coming from a precursor of the glia cell.

36. **Reaction of Pupil to Colored Light.**—Cutting has found that the pupil reacts differently to different colored lights, giving a greater reaction in some than in others in the following order: white, yellow, reddish yellow, green, blue and violet, thus following the luminosity of the spectral colors. There is no reaction specific to different diseases—the same law holds for the paretic as for the hysteric. There is a distinct clinical value in using the green light as a "measure" for amplitude of reaction, which cannot be obtained from white light. It is a convenient method for measuring the amount of light necessary to produce a pupillary response.

107. **Restoration of Gastro-Intestinal Continuity.**—In the method described by Balfour the resection is carried out in the ordinary way with especial attention to such important points as the wide removal of gland-bearing tissue, the avoidance of injury to the middle colic blood supply of the transverse colon, the resection made well beyond the cancer limits. the cauterization of all cut mucous surfaces to prevent cancer cell transplantation, and the secure inversion and burial of the duodenal stump. The first loop of jejunum is procured and a point about 14 to 18 inches from the duodenojejunal

angle is marked. The jejunum is then carried up in front of the transverse colon and omentum and a segment of suitable size is chosen at the point already marked. This section of jejunum is directed so that the proximal end of the loop will be approximated to the lesser curvature of the stomach. A series of interrupted silk sutures in the serosa is used for the first line posteriorly, beginning at the greater curvature. All these sutures are placed before any are tied, and the ends of the top and bottom sutures may be conveniently left as guides. The first suture line is about one-half inch below the clamp on the cut end of the stomach, and on the side of the jejunum about three-fourths inch from the summit of the loop. The jejunum is now incised and the crushing clamp removed from the stomach. Any actively bleeding vessels are ligated. The posterior row of the anastomosis uniting the posterior wall of the stomach to the inner cut edge of the jejunum is of chromic catgut. The stitches on the gastric side should be taken after the edge which has been crushed by the clamp has been trimmed with the scissors. A second row of finer catgut may be used to advantage in the posterior line. The first chromic catgut suture is continued in front in the usual way to complete the closure. An interrupted silk suture line similar to that used posteriorly is placed anteriorly, particular care being taken to reinforce the angle of anastomosis at the lesser curvature. A few interrupted silk sutures are placed where necessary further to protect the anterior suture line and the suture at the lesser curvature, the stump of gastrohepatic omentum which contains the ligated gastric artery being utilized as a support to the gastrojejunal angle at this point.

115. **Nephrectomy for Renal Tuberculosis.**—This paper is based on a study of eighty-seven consecutive nephrectomies for tuberculosis of the kidney. Among these cases there were two deaths within four weeks after the operation and before the patients left the hospital. The cause of the immediate mortality in the first case was probably shock. The second patient lived three weeks after operation, necropsy revealing the fact that the remaining kidney was decidedly tuberculous. Of the cases showing a later mortality, two died of general tuberculous peritonitis, four of pulmonary tuberculosis, while the cause of death in the remaining four is not known. The longest interval between operation and death was seven years, this patient dying of pulmonary tuberculosis at the age of 37. Forty-five patients replied to letters asking for present condition. In 48 per cent. of the cases with painful and frequent urination before operation some bladder symptoms persisted, abnormally frequent urination being the most common. The history of each of these cases showed that bladder trouble had extended over a long period prior to operation. Of the 9 per cent. who reported no definite improvement in the bladder symptoms, each one had pronounced bladder involvement at the time of operation. Twenty per cent. reported that they were in perfect health and all the rest that they were greatly improved. One man, operated on eight years before, reported himself as entirely cured although his history showed that for three years previous to operation he had complained of frequent urination, a symptom which persisted for ten months after the nephrectomy. Pain in the back of a colicky nature was reported by twelve patients, while twenty-five reported pain of varying degrees in the back, side, or hip. Of the entire series forty-four had hematuria. All still had pyuria.

123. **Indigocarmin and Phenolsulphonephthalein Tests.**—Peterson shows that when indigocarmin and phenolsulphonephthalein are excreted simultaneously, the addition of sodium hydrate eliminates the color of the indigocarmin and brings out that of the phenolsulphonephthalein. Phenolsulphonephthalein is excreted by the kidneys in the same amount whether used alone or simultaneously with indigocarmin. The presence of indigocarmin does not interfere with the microscopic study of the specimen of urine. The growth of bacteria is not retarded by the presence of this dye in the culture. Five c.c. of a saturated solution of indigocarmin forms a suitable and safe dose for intravenous administration. A quantitative colorimetric estimation of indigocarmin can be carried out.

8 Case of Contracted Pelvis; Cesarean Section Thrice. A. Crook.—p. 515.

1. **Treatment of Infected War Wounds.**—Summary of Morison's technic: Under an anesthetic, usually open ether, cover the wound with gauze wrung out of 1 to 20 phenol and clean the skin and the surrounding area with the same lotion. Open the wound freely and, if possible, sufficiently to permit of inspection of its cavity. A guide—a finger is the best if the size of the wound permits of it, and if not a thick probe—should be introduced to the bottom of the wound so as to give a good exposure. In doing this special regard must be paid to nerve trunks and muscular branches of nerves, since the division of blood vessels, excepting the largest and of muscles of themselves does little harm as compared with that of the disability following nerve damage. Cleanse the cavity with dry sterile gauze mops, Volkmann's spoon, etc., and remove all foreign bodies. Mop the surrounding skin and the wound cavity with methylated spirit and dry it. Fill up the whole wound with a bismuth, iodoform, paraffin paste, rub it well in with dry gauze. Then remove all excess, leaving only a thin covering over the wounded surface. Dress the wound with sterile gauze and cover all with an absorbent pad, which is held in position by sticking plaster and a bandage. This dressing requires no change for days or weeks if the patient is free from pain and constitutional disturbance. Should, however, discharge come through, the stained part must be soaked in spirit and a gauze dressing wrung out of the same applied as a further covering. Redressing is very simply done. After removal of the old dressings the wound is covered with a dossil of wool soaked in spirit, and the sticky dirty looking discharge is wiped off the surrounding skin until it is clean.

2. **Wound Treatment by Brilliant Green Paste.**—The authors report favorably on the use of the paste introduced by Hey, consisting of brilliant green, boric acid, French chalk and liquid petrolatum. It is said to be nonpoisonous and painless. In the great majority of cases it almost completely sterilizes the wound in three days, so that secondary suture can be performed even in large wounds complicated by bony injury. Small, completely excised wounds can be sutured primarily. The wound need only be dressed about once in four days. No permanent residue is left to interfere with immediate healing. By this method they have been able to obtain healing within a fortnight of cases of compound fracture even when complicated by joint injury, big buttock wounds and deep muscle wounds. They have excised an elbow joint full of pus, and obtained primary healing in a fortnight.

3. **Liquid Petrolatum in Treatment of Wounds.**—The results of observations carried out in several casualty clearing stations, Gray says, show that liquid petrolatum has, almost without exception, a very beneficial action on the walls of a wound and on the tissues adjacent to the wound. It prevents development of the symptoms of inflammation in these parts and will cause such symptoms to disappear rapidly if they are already present. The skin remains or becomes normal in appearance; redness and swelling do not develop or, if present, disappear. Pain is assuaged. Performance of function becomes easier, although, of course, this is frequently restrained by therapeutic agencies and is therefore not evident.

Changes of dressings are comparatively painless. Liquid petrolatum is not antiseptic in the ordinary sense of the term. If a wound be "packed" with gauze wrung loosely out of the petrolatum, it is found that in two to four days the discharge in the wound swarms with organisms, although the surrounding parts are free from inflammation. The "wound" with the fluid part of its contents may be likened to a test tube containing nutritive medium in which organisms are thriving. In either case the addition of antiseptic will lessen or entirely inhibit the growth. If an antiseptic is dissolved or suspended in the liquid petrolatum with which the gauze pack is saturated, it is found that the wound remains or becomes sterile. Various antiseptics or mixtures of antiseptics have been used, with good effects in all cases, although these effects vary, possibly owing to selective effect of the particular antiseptic against the particular organism or to tolerance acquired by the organisms for the antiseptic employed against them. Those chiefly used up to the present are flavine, brilliant green, boric acid and iodoform. It is rather difficult to justify preference for any one. A combination seems desirable.

5. **Medicinal Treatment of Gonorrhea.**—Donald and Davidson claim that medicinal treatment of gonorrhea from a clinical and statistical point of view undoubtedly does not help but retards the cure of gonorrhea, and tends to produce chronicity.

11 *Case of Espundia (Naso-Oral Leishmaniasis) and Three Cases of Kala-Azar in Sudan Treated by Intravenous Injection of Antimonium Tartaratum. J. B., Christopherson.—p. 229.
12 Generalized Vaccinia in Sudan Natives. A. J. Chalmers and R. G. Archibald.—p. 236.

11. **Espundia and Kala-Azar Treated by Intravenous Injection of Antimonium Tartaratum.**—Considering the difficulties which may be encountered in the operation of introducing the drug into the lumen of the vein in kala-azar patients, Christopherson advises that the smaller the quantity of fluid and, therefore, the smaller the syringe and needle required, the better, and therefore quantities which can be introduced with a hypodermic syringe with a rather large hypodermic needle are the most convenient. Stronger solutions than one-half grain to 20 minims of distilled water are liable to be irritating (1 grain tartar emetic to 40 minims sterile normal salt solution, or distilled water, can conveniently be made up and kept in a flask). As routine treatment 20 minims of such a solution may be injected, and if this is well stood, may be increased to 40 minims on the following day, and then every other day and increase of 10 minims each dose till 2 grains is reached. This for a couple of months, and then once a week for some time after. For practical purposes 3 grains may be taken as the maximum dose. The most noticeable clinical sign is the change in the native patient's skin from the dark, dirty, dry appearance characteristic of kala-azar patients, as if they had been washed with dirty water, to the normal, moist, sleek, supple condition. Increase in body weight is very noticeable. Temperature falling by lysis commences to fall a day or two after commencing injections, and reaches and remains at normal in about a fortnight. Christopherson has had good results from the use of this drug.

Lancet, London

21 Occurrence of "Blue Pus" in septic Wounds. T. H. Kellock and C. R. Harrison.—p. 605.
22 Case of Strangulated Femoral Hernia. T. E. Coulson.—p. 606.
23 Case of Extra-Uterine Gestation. E. A. Constable.—p. 607.

14. **Sterilization by Dakin's Solution and Occurrence of Secondary Hemorrhage.**—It would appear from Bashford's experiments as if the local action of Dakin's solution was held in check by an efficient circulation either by providing protein containing fluid or by carrying off and rendering harmless the hypochlorites as they approach living tissues without entering into combination with them, that is, killing them.

18. **Relation of Cerebrospinal Fever to Positive Contacts.**—Fildes and Baker maintain that the case of cerebrospinal fever is not specially responsible for the spread of the disease and is infected by one of the positive contacts. They look on the patient as one of the rare individuals who cannot confine the meningococci to the nasopharynx and merely "carry." Their results also appear to indicate that in such a case the cocci pass very rapidly to the central nervous system after gaining access to the nasopharynx.

20. **Nervous Cretinism.**—The nervous symptoms that are associated in the child with atypical athyreosis, Crookshank says, are to be recognized as forming degrees of the state described by McCarrison as "nervous cretinism." "Nervous cretinism" occurs in England, possibly endemically, but certainly, if not sporadically, at any rate without obvious endemic associations. In almost every case that Crookshank has seen which appears to deserve the appellation of "nervous cretinism," there has been evidence of dysthyreosis in the mother or other members of her family. The earliest manifestations of mild "nervous cretinism" are generally regarded as tetany, and occur toward the end of the second year of life (or a little later), when the child has well learned to walk and talk. Following the tetany—or stage of remittent spasm—there may ensue a stage of weakness, with tottering gait, and a more persistent spasm that passes into a condition not to be distinguished from congenital spastic diplegia or Little's disease of moderate degree. In the more severe cases mental defect is obvious almost from very early days, and the early appearance of spasm with nystagmus leads to the confident diagnosis of congenital spastic diplegia.

The relation of these cases to the group of mild nervous cretinism is shown by the familial dysthyreosis and by the at least partial response to thyroid medication; sometimes by familial incidence. The mild cases whose nervous symptoms first attract notice toward the end of the second year or thereabouts are not cretins in the ordinary sense of the term, and frequently in the beginning are docile and pleasing children. They are sometimes, however, broad-headed and their hypothyroidal quality may be manifest in the arrangement of their forehead and hair and eyebrows, and in the waxen puffiness of their skin. No claim is made for the cure of established cases of Little's disease or congenital spastic palsy by thyroid tablets; but certain cases of young children, diagnosed by specially competent physicians as congenital spastic diplegia with amentia, have definitely responded to treatment by thyroid; while cases of tetany, spasm, weak legs and so forth, recognized as corresponding to McCarrison's milder cases of nervous cretinism, have become quite cured while taking the same substance. The effects, on similar cases, of parathyroid medication, Crookshank has not yet noted.

Archives des Maladies du Cœur, etc., Paris

September, X, No. 9, pp. 401-448

24 *Athlete's Heart. J. Heitz.—p. 401.
25 *The Soldiers with Disordered Action of the Heart. L. Gallavardin.—p. 408.

24. **Athlete's Heart.**—In Heitz' case the athletic proprietor of a physical culture studio had a very large heart of the type described by Shumacker and Middleton in The Journal, April 11, 1914, as the effect of immoderate athletic sports, and

by Tørgersen in ski jumpers—a hypertrophic dilatation presumably from professional strain. But roentgenoscopy showed the aorta likewise dilated, and the Wassermann reaction was positive. The man had never had malaria or other severe infection or drinking habits; there had been a single dubious chancre ten years before but no other pathologic manifestations at any time until recently there had been some symptoms from the hypertrophied heart. This case and others cited by Heitz confirm the view that athletic training is harmless only when the myocardium has not already been damaged by some infection or intoxication. On account of the paucity of the information available in this line, strict supervision is necessary for athletes training for competitive events. It is not enough to count the pulse, measure the blood pressure and auscultate the heart, the subjective reactions must be investigated, and the thorax examined with the roentgen rays. The training should be stopped at once in case of indisposition. Those with a history of malaria or syphilis should be warned to give up training altogether when the cardiovascular apparatus seems to have been touched by the disease.

25. **The "Tachycardiacs."**—Gallavardin reproduces with comment most of the report recently published by the British Medical Research Committee on the soldiers returned as cases of "disordered action of the heart" or "valvular disease." In 150 cases in his own experience, the condition was serious in only two, the pulse from 110 to 150 and the blood pressure 170 to 180 mm. mercury; in all the rest no organic cause for the tachycardia could be discovered. In the grave forms the pulse ranged about 100, the pressure 160 mm., but even climbing one flight of stairs sends the pulse up to 170 or 180, and it does not subside to the former figure for five minutes or more. Sedentary service has to be found for the men in this class. Below the moderate cases, in the mild group, the pulse keeps between 60 and 80, occasionally reaching 90, with pressure of 140 or 145 mm. It may run up to 150 but subsides to the former figure in a few seconds after reclining. Men in this group can be set to driving artillery wagons and the like, to spare them from wearing a knapsack and long marching.

Gallavardin comments on the large numbers of these "tachycardiacs" we are encountering when before the war we had scarcely a suspicion of this vast field of nonorganic cardiac pathology, this tribe of men with palpitations, shortness of breath, and disordered action of the heart with no organic lesion to be found. He emphasizes that the war did not create this category of "cardiacs"; it merely has revealed them. These "cardiacs" existed just the same before the war, but they never felt the need for consulting a physician on this account, and merely sought light occupations behind counters, etc. The profession at large knew nothing of this army of nonorganic tachycardiacs, and the army physicians seem to have paid no heed to these men who were constantly dropping out of long marches and excused from carrying the knapsack. Those that did not drift into sedentary services were discharged from the army labeled endocarditis or hypertrophy of the heart. Consequently the profession during the first year of the war was amazed and skeptical at the wholesale dismissals from the army for endocarditis, tachycardia, etc., when the most skilful auscultation revealed nothing wrong. But they had to yield to the evidence, and recognize that there is a whole series of physical disabilities in this line—at least partial disability—which is at least as important as that due to organic heart disease. Infectious diseases have a great influence on the development, or rather the aggravation of these tachycardia neuroses, but a constitutional nervous predisposition is plainly evident in most of the cases. The overexcitability of the sympathetic system is not confined to the heart innervation.

He compares his 150 cases with those analyzed by the British committee, saying that time alone will tell the future of these cases. Aside from the graver cases, he does not think there is serious danger for the heart. Their rapid heart beat makes them poor runners, just as their emotional instability and trembling make them poor marksmen. Their dyspnea from exertion is never accompanied by hypertrophy or dilatation of the heart. The probabilities are that this overexcitability of the nervous system will calm down as they grow older. He queries whether this special circulatory excitability may not predispose to vasomotor paralysis in the course of various infectious diseases, and thus be responsible for the fatal outcome. The tachycardia is regularly paired with hypertension, and this may be an element of danger, setting up stable processes of hypertension. Still further peril lies in the possibility of actual organic disease developing in a heart overworked by this tachycardia. He adds that in 500 young men, all free from organic valvular disease and tuberculosis, the pulse rate during the revision examination was from 50 to 75 in 2.6 per cent.; from 75 to 100 in 25.6; 100 to 125 in 36.6; 125 to 150 in 27.2, and from 150 to 175 in 8 per cent. All of course were emotionally excited, but the figures illustrate the wide individual variation.

July-September, VI, No. 7-9, pp. 193-272

26 Combined Rupture and Inversion of the Uterus. A. Brindeau.—p. 195.
27 *Elderly Primiparae. B. J. Kouwer (Utrecht).—p. 207.
28 Postpartum Eclampsia. E. Hauch (Copenhagen).—p. 224.

27. **Elderly Primiparas.**—Kouwer tabulates the findings in respect to 5,300 primiparas which demonstrate that the average duration of labor is from 16.6 to 17.1 hours in young primiparas, but jumps at once to 21.6 up to 25.9 hours in the elderly primiparas. The frequency of forceps deliveries increases in the same proportion. This longer duration of labor is probably, he says, the consequence of the functional enfeeblement of all the organs, including the endocrine glands which act on the uterus. This enfeeblement he ascribes to the delay in the physiologic development of the genital organs and endocrine glands, as the interval has been so long between the onset of menstruation and the completion of the cycle of functional development of the uterus. It is not necessary to assume any histologic changes in the soft parts; the trouble is merely inertia. But the amazing feature of his tabulation is that the dividing line-marking off the elderly primiparas is at the age of 24. Below this, labor is physiologic; at 24 the duration averaged 21.6 hours, instead of 15.9 at 22, among 1,831 primiparas in his service. A similar dividing line of the "elderly" under 28 was evident in 3,460 primiparas at the polyclinic although the records there are not kept with equal care. An interval of six or seven years between the first menstruation and the first pregnancy ranks the woman among the "elderly."

Bulletin de l'Académie de Médecine, Paris

29 The Declining Birth Rate. Pinard and others.—p. 303. Continuation.
30 *Heart Accidents from Asphyxiating Gases. C. Fiessinger.—p. 322.
31 *Rubber Prosthesis for the Humerus. P. Delbet and Girode.—p. 328.
32 Therapeutic Action of Colloidal Sulphur. A. Cawadias.—p. 329.

30. **Heart Disturbance from Asphyxiating Gases.**—Fiessinger calls attention to the action on the heart of the new asphyxiating gases. They seem to be more complex than the chlorin gases which act on the respiratory tract. . Their effects are more like those observed in the laboratories studying the fixation of nitrogen or in the manufacture of nitric acid. The industrial intoxication is slow and prolonged, while the intoxication from the drift gas is sudden and fulminating, but the symptoms in both are of the same cyanogen compounds type, syncopes with slowing of the pulse. This syncopal tendency is manifested at the slightest movement for months. One officer while on duty at an advanced post became intoxicated with this type of gas and was accused of simulation during the following months until the nature of his disturbances was differentiated.

With this sudden intoxication the man notices merely a fruity, apple-like odor in the air; then suddenly he feels benumbed, his limbs give way, and he feels a burning from his throat down to the pit of the stomach. Then come vomiting and drooling; increasing vertigo, the extremities icy; and unconsciousness follows, sometimes for several hours.

The pulse next day was retarded in the cases Fiessinger has seen, dropping at times to 25 or 30, but others have noted acceleration up to 100. The heart beat is weak and seems remote to the ear, but regular except occasionally a dull sound suggesting an auricular contraction not transmitted to the ventricle. The men have to lie horizontal, a syncope coming on at the least attempt to sit up. After from three to six months the pulse returns to its normal rate and, except for extreme weakness, the man can resume his ordinary life. Two soldiers presented a somewhat less grave clinical picture than this, and after their convalescence furlough had been extended one month they were almost entirely cured.

The symptoms in these cases gave the clue to the intoxication of a chemist experimenting in an industrial establishment with fixation of nitrogen from the air on aluminum, calcium and other bases, at a temperature of 1,850 C. In this case there was no appreciable improvement for a year, during which he was compelled to retain a horizontal position. At times his pulse dropped to 12; even when it was 40 the syncope returned when he attempted to sit up. With mild poisoning there are merely dizziness and slowing of the pulse. This is the cause of intoxication from automobile gases. The carbon monoxid cannot be incriminated as the amount is too small; the products of incomplete combustion of hydrocarbons seem to be exclusively involved. They act on the medulla and fatal cases are known in touring cars. Fiessinger has had several mild cases of the kind among chauffeurs; at first he ascribed the symptoms to stomach trouble and nicotine. He advises treatment of the acute intoxication with venesection and injections of etherocamphorated oil. Later the stomach should be treated with bismuth if there is hypersthenia, and the heart disturbances, when accompanied by syncopes, with theobromin and small doses of caffein. Small doses of strychnin may also render service, and bed rest should be maintained for months. Heart tonics, such as digitalis and strophanthus, seem to aggravate the condition. Some have reported benefit under epinephrin, but Fiessinger has had only uncertain results with it. In the discussion that followed, Pouchet remarked that the waste gases from automotors must be reckoned with now as one of the factors that detract from the healthfulness of city life.

31. **Rubber Artificial Humerus.**—Delbet and Girode bridged the long gap after resection of the humerus for sarcoma with a rod of hard rubber 15 cm. long. At the head end it was 5 cm. in diameter and only 21 mm. in the shaft. This endoprosthesis was introduced ten days after removal of the tumor. The piece proved a little too short and it had to be fastened to the lower stump with a wire instead of fitting into it as intended. The artificial humerus seems to be answering every purpose to date, two and a half months later, the arm rendering good service.

33 Technic for Extracting Projectiles in the Skull or Spine. C. Villandre.—p. 593.
34 *Radiodiagnosis of Horseshoe Kidney. N. Voorhoeve (Amsterdam).—p. 599.
35 Radiologic Diagnosis of Fracture of the Spine in Men *Buried* under Débris. G. Détré.—p. 603.
36 The Electric Psychic Reflex. A. Zimmern and B. Logre.—p. 610.
37 Importance of Early Roentgen Diagnosis of Tibiotarsal Dislocation. Bec and Hadengue.—p. 620.
38 Technic for Locating Projectiles in the Tissues. A. Chéron.—p. 621.

34. **Radiodiagnosis of Horseshoe Kidney.**—Partial fusion of the two kidneys should be suspected when the inner margin of the kidney is parallel to the spine and the interval between is abnormally narrow. The lower margin on both sides is also abnormally low, and the kidneys cannot be moved to and fro although axial movement may be possible. The lower poles of the horseshoe kidney are necessarily closer to the abdominal wall than the spine, while with normal kidneys they are back of the anterior plane of the vertebrae. This aids further in differentiation as there is an apparent displacement of the lower margin of the kidney with ventrodorsal roentgenoscopy, different from what is observed with normal kidneys.

43 *Capillary Drainage of the Spinal Cavity. R. A. Gutmann.—p. 269.
44 Intravenous Injections of Quinin in Treatment of Malarial Cachexia. P. Lafosse.—p. 270.

39. **War Wounds of the Knee.**—Schwartz protests against the frequent practice of incising the capsule and severing the patellar ligament unless conditions absolutely compel this. It is often possible to clear out the wound from the side of the knee, leaving the patellar ligament intact. This should be the routine practice when the bone has not been fractured. With shattering of the bone, resection is inevitable and it takes a long time for the lesion to heal with solid consolidation in a good position, and the man will find it painful and tedious. However, a solid, straight leg with good ankle joint, is far preferable to all the artificial legs in the world. Hence, even when the knee has been badly shattered, he makes every effort to save it from amputation.

40. **The Circulating and Stationary Mass of the Blood.**—Prével argues that the influence of gravity on the circulation of the blood has not been paid the attention it deserves. Even in normal conditions the mass of the blood must be regarded as in two parts, one actively circulating and the other stagnating in peripheral vessels. The actively circulating mass of the blood is all that is evident in the erect position. Under the influence of gravity, as the subject stands still, the blood stagnates, especially in the peripheral vessels. Prével describes means by which we can estimate the proportional bulk of the orthostatic circulating and the stagnant blood. General massage on the reclining subject is probably the most effectual means for getting all the blood to circulate. The proportion of stagnating blood naturally increases with defective heart or vessel action. Determination of the proportion thus shut-off from the blood stream may afford valuable information in nervous shock after war wounds. His device for the purpose is a dial attached to the Pachon oscillometer.

43. **Capillary Drainage of the Spinal Cavity.**—Gutmann introduces into the spinal cavity six or seven silk threads, fitting them into the Potain needle with which the lumbar puncture has just been made. Once in the cavity, the free ends of the threads hold them from slipping back as the needle is withdrawn. The indications for this effectual capillary drainage are met with in septic meningitis, and he urges others to give it a trial.

49 Solutions of Quinin for Injection. R. Dalimier.—p. 541.

45. **Chronic Enteritis and Military Service.**—Laubry and Marre comment on the difficulty of determining the fitness for service of men with bowel trouble. The general condition is the chief element in the prognosis; the weight and the temperature are more important than the laboratory findings. The tendency is to discharge from the army the men with chronic enteritis, but many of the men encountered in the hospitals in the home zone are declared cured about ten times a year. When there is merely colitis with constipation, and the general condition is good, the men should be kept under observation or sent back at once to active service. If the general condition is precarious or is growing worse, a temporary relief from army duties is indicated. If under surveillance and proper measures improvement does not follow and a special diet is required, the men should be temporarily relieved from active duty or be assigned to light duty. They urge revision of the decision at the end of three months, but insist that as much care and attention to detail should be applied at the revision as at the first examination.

A compulsory sojourn in a specialist hospital service, giving opportunity for thorough examination, should precede the final revision. This is the only way to avoid the numerous vexatious and expensive blunders made in the past.

46. **The Plantar Reflexes with War Wounds.**—Rimbaud seeks to systematize and estimate the importance of the reflexes induced by tapping the sole. The plantar flexion of the whole foot is identical with that of the Achilles reflex and has the same mechanism and significance. In hundreds of tests he always found this reflex abolished when the Achilles reflex was gone. Besides this tendon reflex, there is a muscle reflex, the flexion of the toes, which corresponds in the same way to the reflex induced by percussion of the tibialis anticus. Both of these reflexes give information in regard to the condition of the sciatic nerve, and especially of its popliteal branch. The disappearance of the flexion of the foot is an early sign of some lesion in the sciatic nerve, earlier even than loss of the Achilles reflex, as it is more sensitive than the latter. The toe reflex is abolished only when there are grave lesions or disease in the main sciatic or popliteal nerve, practically blocking the nerve. The loss of any muscle reflex indicates a grave lesion. With some slight lesion of the sciatic nerve, the flexion of the foot reflex may be abolished while the toe flexion is exaggerated. This plantar dissociation is thus a reliable sign of some lesion of the sciatic nerve but also that it is mild. It is thus an important guide in treatment of wounds of the thigh, etc.

52 Present Status of Treatment of War Wounds. A. Demmler.—p. 303.
53 Extraction of Projectiles under Screen Control. R. Didier.—p. 306.

50. **Diabetic Polyneuritis.**—Pitres and Marchand relate that, judging from their experience, diabetic polyneuritis develops just like ordinary polyneuritis of toxi-infectious origin. The prognosis is generally favorable. The toxic products developed in the course of the diabetes act on the nerves like any other toxic products of similar virulence. In a case described at length, ecthyma and gingivitis were the first warning symptoms of the disease. Then sugar was discovered in the urine and later the polyneuritis developed. It assumed a quadriplegic form, but it subsided as the glycosuria was brought under control. The patient was a man of 47; the painful hyperesthesia and paroxysms of pain had been most pronounced in the legs, as also the paralysis.

51. **Wire Ring for Shattered Bone.**—Sénéchal ties a wire around the sequesters and bone to bring the pieces into their proper relations, and relates that this wire *cerclage* has been applied in sixty-six cases to date. Sometimes he uses two or three of the wire rings. The history of some typical cases, with the roentgenograms, shows the advantages of this method of bridging the gap. He does not try to reconstitute the bone shaft, but bridges the gap with the bunched sequesters. The aim is to have the sequesters serve as a kind of splint to hold the parts in place. The plaster cast is fitted on at once, while the patient is still under the influence of the anesthetic. He always uses an open cast with high metal loops spanning the gap left at the site of the wound.

54 *Results of Suprapubic *Prostatectomy.* F. Suter.—p. 1220.
55 Bacillary Dysentery in Switzerland. Hunziker.—p. 1226.
56 *Factitious or Real Disease. A. Haslebacher.—p. *1232.*

54. **Suprapubic Prostatectomy.**—Suter states that in his seventy-five operative cases of suprapubic prostatectomy, one patient succumbed to embolism, two to insufficiency of the kidneys and two to heart disease. The other patients all recovered and the results were excellent, aside from this mortality of 6.7 per cent. Even with the best of technics, the operation is not free from danger, but he advocates it for all just entering on regular catheter life. Especially for the younger *prostatikers,* he says, this technic is preferable as the prognosis is better in the young, while they will have more years in which to enjoy their release from prostate trouble.

56. **Differentiation of True from Factitious Painful Affections.**—Haslebacher comments on the common neglect of digital palpation in cases of alleged muscular, nervous and traumatic lesions. Palpation is usually most instructive in the very cases in which other methods of exploration have the least to show. We should never neglect an opportunity to exercise and perfect the "eyes in our fingertips." When a war wound or other injury does not heal in the usual time with restored function, some complication is responsible, irritation of nerves, development of adhesions, spastic hypertony, stagnation of blood in certain veins, or exudates or deposits in joints. Whenever a nerve is suffering at any point in its course from any of the above troubles, the circulation in the nerve is interfered with, and there may be pain, anesthesia or other symptoms at or near or remote from this point, which is always more or less tender. He seeks the tender point by making spiral movements with pressure around the suspected point. When it is reached, the finger feels a slight contraction and the patient makes an uncontrollable expression of pain and the parts under the fingers may stiffen. As every one of these nerve points has its own symptoms, so every symptom can be followed to its nerve-point source. The most commonly involved nerve points are in the orbit, temple, mastoid process, in the neck at the trachea or thyroid, in the interspaces, the ileosacral region, the pelvis, the inside of the thigh, the knee and the malleoli. Anemia, gout, rheumatism and arteriosclerosis are the principal causal factors, aside from trauma, and discovery of these tender points confirms the reality of the disturbances complained of. This is the main field for physicotherapy, especially massage and heat. In chronic cases, a severe aggravation of the symptoms follows after a few days, usually in the second week. This aggravation is almost infallible testimony to the reality of the trouble. If it does not occur after energetic treatment for ten or fourteen days, we have good reason to suspect the truth of the patient's complaints, unless he is so debilitated that the organism cannot be aroused to fight the disease.

67 *Indicanemia. A. Fara.—p. 421. Commenced in No. 9, p. 385.

59. **Epidemic Meningitis.**—Paleani emphasizes the importance of making the serum from the strains of meningococci found in the cases during the epidemic. When the cerebrospinal fluid was found limpid and sterile, he took cultures to make the antiserum from the nasopharynx. For prophylactic purposes, the nasopharyngeal secretions were all that was necessary. There are liable to be numerous pseudomeningococci and parameningococci, but agglutination generally identifies them. The findings were positive in only thirty of the forty-three specimens of cerebrospinal fluid sent to him for examination during the last five months. In the other specimens pneumococci or tubercle or other bacilli were found, or else the case proved to be one of meningeal involvement in mumps, or embolic softening of the brain. True epidemic meningitis usually has more or less of a septicemic character

and he consequently administers the antiserum subcutaneously as well as intraspinally, and he advocates fairly large doses daily.

61. **Fracture of the Femur.**—Schiassi warns against extension with weights when the stumps are not exactly coaptated after simple fracture of the femur. Roentgenoscopy has shown that only approximately normal conditions are restored by this means. When a fracture with overlapping stumps has been reduced under general anesthesia, the plaster cast should include the foot and entire leg, the root of the other thigh and the whole of the pelvis. Roentgenoscopic control of the reduction is indispensable. If there is no suspicion of infection, this can be done while the patient is still on the operating table, before the cast is applied, examining the reduction from both the front or rear and the side. No antiseptic to date can arrest established infection in a fracture. The focus must be cleared out and drained, a counter opening made on the side opposite the wound. The leg should be immobilized but even an open plaster cast cannot be applied until the infection has become attenuated. He discusses further the technics suitable for the different varieties of fracture.

66. **The Oculocardiac Reflex.**—With a single exception, Fumarola's findings confirmed those of others in respect to the presence and significance of the oculocardiac reflex.

67. **Indicanemia.**—Fara reviews the literature on indicanemia and affirms that the evidence to date testifies that indicanemia is physiologic. It assumes pathogenic importance only when it is above the normal range. When speaking of it as a pathologic phenomenon it should be styled hyperindicanemia. In forty persons with various diseases and the healthy controls—all without azotemia—the indican content of the blood ranged from 0.32 to 1.6 mg., fluctuating besides with the diet. In one healthy subject it ran up from 0.64 to 1.28 mg. a few hours after eating 300 gm. of meat. The azotemia findings never fluctuated parallel. In thirty-two cases of nephritis without uremia, the indicanemia reached 1.67 mg., and in twenty-eight with uremia it reached 4.27 per thousand. The Obermayer technic is best for detection of indicanemia in the clinic, as it does not begin to give positive findings until the indican content is above the normal range, and thus it testifies to defective elimination by the kidneys.

71 Present Status of Rat-Bite Fever. G. Molinari.—p. 944.

68. **Primary Gonococcus Prostatitis.**—Porcelli's patient complained merely of a sensation of cold localized in the urethra its entire length, but nothing could be found to explain it, and he grew thin and neurasthenic. Closer examination revealed a chronic prostatitis, and gonococci were cultivated from the pus expressed. There was no history of gonorrheal urethritis, and there was much to suggest that the prostatitis was primary and had induced the sexual neurasthenia.

69. **Aleukemic Lymphadenia.**—The special feature of the case described was that the hypertrophy of lymphatic tissue first became apparent during convalescence from a mild case of mumps.

82 *The Roser-Nélaton Line. I. Motoshima.—p. 269.

81. **Lipoid Products of Destructive Metabolism in Degenerating Nerves.**—This report of Shionoya's extensive experimental research in this line is accompanied with two colored plates showing the contrast staining in sixty-seven different specimens. In most of the experiments the nerves were crushed but in a few they were cut. The work was done on cats and dogs.

82. **Nélaton's Line and the Hip Joint.**—Motoshima remarks that many physicians trust to the line connecting the anterior superior iliac spine and the tuberosity of the ischium as the mariner trusts his compass. They assume that invariably the tip of the greater trochanter is crossed by this line when the longitudinal axis of the femur is held at a right angle to the line. When the trochanter extends above this line, pathologic conditions are assumed as infallibly responsible for this. Motoshima has been studying the anatomic relations between them in 114 persons and measurements on numerous cadavers. The minute details of all are tabulated. They show that the irregularity of the basal points renders uncertain any deductions therefrom, especially when there is a history of rachitis. The greater trochanter extends above the line in normal conditions when the shaft of the femur is at a right angle. As a guide to the region we can accept the line as crossing the point of the greater trochanter at the point where it can be most readily palpated.

86 The Domain of Psychanalysis. G. J. Huet.—p. 700.
87 Recurring Intrameningeal Hemorrhages Simulating Meningitis in Apparently Healthy Young Physician. P. B. Westerhuis.—p. 702.

83. **Do Animals Feel Pain?**—The first part of van Rijnberk's study of this question was reviewed in these columns last week, page 1745. He here cites further examples, such as that if the tail or part of the body of a honey-sucking bee or male copulating shrimp or frog is cut off, the creature continues undisturbed to suck honey and the male does not release the female from his embrace. The twitching of the skin of a horse is a reflex action which occurs the same if the communication with the brain is shut off. He says further that veterinarians report that quite a considerable operation can be done on the large, herbivorous domestic animals while they are feeding and they may continue feeding without interruption. Dogs, cats and rabbits after severe operations in the laboratories are as lively and frolicsome as before so soon as the effect of the general anesthesia has passed off. He adds that dogs cannot be trained by the eyesight alone; there must always be some pleasurable or disagreeable experience connected with the act in which it is being trained. Even in man, he continues, the sensation of pain seems to be restricted to the outlying parts of the body. It is still a question whether sound organs in the thoracic and abdominal

cavities are sensitive to pain. "In short," he concludes, "the attempt to answer the question 'Do animals feel pain?'—which the layman answers glibly in the affirmative—is to step on a treacherous trapdoor which drops one into a hornets' nest of philosophy, psychology and biology."

Hospitalstidende, Copenhagen

September 5, LX, No. 36, pp. 861-884

88 *Gastric Cancer Simulating Malaria. C. Rovsing.—p. 861.

88. **Gastric Cancer Simulating Malaria.**—In both of the two cases described there were long paroxysms of fever, accompanied by vomiting once each time but with no other indications of digestive trouble. The first patient was a sailor, 47 years old, who began four years before to have attacks of fever, running up to 102 or 104 F. Then he vomited and the fever subsided. These attacks returned every third day for a time. Later the intervals became much longer and irregular. After two years of freedom they returned at three or four day intervals. There were never any signs of jaundice, and the bowel functioning seemed to be always regular. During the febrile periods he complained sometimes of pains in the lumbar regions and spine, but there was never hematuria or sand in the urine. The febrile attacks had been ascribed in turn to malaria, septicemia, pyelitis and cystitis, but finally, by exclusion, attention was focused on the stomach although no tumor could be felt. The functional tests and roentgenoscopy revealed stenosis of the pylorus from cancer.

The other patient was a man of 49 who began to have chills followed by fever running up to 104 F., occasionally accompanied by vomiting. These febrile attacks returned every third or fourth day but sometimes the fever kept up for four or five days at a time. He was treated with quinin and arsenic for malaria without results, and no parasites were found in the blood. By the fourth month he began to have a sensation of oppression in the epigastrium, nausea and vomiting after meals, with occult blood in the stools. The man was restored to clinical health by resection plus gastroenterostomy, and he survived for over three years before death from recurrence of the adenocarcinoma. At the first operation it was found to have involved both stomach and duodenum and some lymph glands, and it pressed against the pancreas. Rovsing has found five similar malaria-like cases of gastric cancer on record. One (Halla) was a necropsy surprise after ineffectual quinin treatment of "four day fever." In one of Hampeln's three cases the patient was dismissed from the hospital as the "malaria" had proved refractory to a course of quinin treatment, but the man returned three months later with a large tumor in the epigastrium. Necropsy confirmed the cancer but no metastases could be discovered. In his other cases the cancer was evident along with the malaria-suggesting symptoms.

The lack of symptoms of dyspepsia in the early stages in these cases is misleading. In Bühring's case (1889), there were no symptoms except those suggesting malaria to the very end; necropsy disclosed an ulcerating carcinoma and abscess in the frontal lobe. This was the only one of all the cases mentioned in which there was anything to suggest pyemia. If the fever is due to absorption of a toxin produced by the cancer, one would expect to find it continuous. More probably the toxic products generated in the stomach from the retention by the closed pylorus caused the fever when they reached a certain level. The vomiting cleared out the stomach, and there was no more trouble until this level had been reached again in the course of three or four days. This assumption is corroborated by the fact that Rovsing's first patient had one or two of the febrile attacks while convalescing from the operation, each yielding immediately to lavage of the stomach. The fever is thus not a contraindication for operative measures as the cancer itself is not directly responsible for it. The prognosis of these cases is comparatively good as is evidenced by Rovsing's first case. There had been symptoms for four years and the man has been in fine health to date since removal of the adenocarcinoma in June, 1916. It was a papillomatous tumor displaying little tendency to grow down into the depths, and was sharply circumscribed, although spreading over the lesser curvature, mostly on the rear wall and pylorus.

Ugeskrift for Læger, Copenhagen

August 30, LXXIX, No. 35, pp. 1439-1478

89 *Habitual Rectum Constipation V. T. E. H. Thaysen.—p. 1439. Commenced in No. 34, p. 1398.

89. **The Clinical Picture with Rectum Constipation.**—Thaysen, in this fifth article on habitual constipation, discusses only the clinical and roentgenologic aspects of what he calls rectum obstipation. He emphasizes that chronic constipation is not accompanied by pains unless the colon is involved, and predominantly the ascending colon. As with the latter the pains are restricted to the right iliac fossa, they are often ascribed to chronic appendicitis. Of his thirty-two patients with this "ascending constipation" the appendix had been removed on account of the persisting pains in seven. In his total series of 112 patients with chronic habitual constipation, appendicectomy had been done in eleven cases and without improving conditions in any instance. When the descending colon is involved with rectum constipation, there is usually tenderness in the left side. The pains assumed the character of colic pains only in 6 of his total 112 cases. In these 6 cases of spastic rectum constipation the different parts of the colon were involved in about the same proportions. Thaysen agrees with Pinkus that the disturbances from habitual constipation are often erroneously ascribed to gynecologic lesions.

In discussing the causes of habitual constipation, he relates that in six healthy persons repeatedly examined by rectoscopy or roentgenoscopy and digital exploration of the rectum, it was never found entirely empty. The accumulating feces could stay in it for eight hours during the day and fifteen hours including the night without inducing a desire for defecation. This suggests that the reflex inducing defecation is not started by contact of the rectal mucosa with fecal matters, as some believe. This and other facts cited, seem to demonstrate that the defecation impulse proceeds from the central nervous system, started by some reflex from the digestive tract, the change to an upright position in the morning or from pylorus functioning after a meal. The physiology of the sphincters is complicated, three centers having been already found that seem to regulate it, one in the sympathetic nerve ganglia in the pelvis; one in the sacral nerves, and—in apes—one in the anterior central convolution. The mechanical effect of straining at stool is reenforced by a deep inspiration position of the diaphragm and by the contraction of the pelvic floor muscles which holds the pelvic organs up and prevents their sliding down. Weakening in any of these factors favors constipation, and also the unphysiologic high seat of the water closet.

He gives the details with the roentgen findings in 6 cases of the different types of rectum constipation, that is, retention of a considerable amount of feces in the rectum for two days without defecation. Sagging of the transverse colon does not seem to be an appreciable factor in constipation of this portion of the bowel. The distance from the umbilicus was less than 5 cm. in 2 cases of this type in men, and in 6 men and 9 women with retention any where in the colon. In 4 men and 5 women with this latter type, the distance was from 6 to 9 cm.; in 9 women it was from 10 to 12, and in one woman 13 cm. One of his tables giving the details of 74 cases of rectum constipation shows that there were no pains in 20 of 29 pure cases; no pains in one of 8 cases of the same, plus retention in the ascending colon; in one of 3 cases of rectum constipation plus retention in the transverse colon, and none in 17 among 34 cases of rectum constipation plus retention in various portions of the colon from cecum to sigmoid flexure. With pure constipation in the ascending colon, pains were pronounced in 19 of 23 cases. In none of his cases of rectum constipation did he ever find the rectal sphincter abnormally contracted, not even in his 6 cases of spastic rectum constipation, but he noted an unmistakable spasm of the sphincter in 3 nervous patients with no tendency to constipation. Sphincter spasm can generally be traced to an anal fistula or hemorrhoidal tumor.

THE CLINICAL COURSE AND THE DIAGNOSIS OF TRACHOMA

M. H. FOSTER, A.M., M.D.
Surgeon, U. S. Public Health Service
BOSTON

Trachoma may be described as a specific, transmissible, destructive inflammation of the conjunctiva, characterized by the formation of the so-called trachoma granulations, which may be either papillary or follicular; the ultimate formation of scar tissue; marked chronicity, and intractability to all forms of local treatment.

Various inflammations of the conjunctiva give rise to the formation of follicles that cannot be distinguished by inspection from those caused by trachoma; hence the formation of scar tissue is the one all important diagnostic feature of the disease. If trachoma had been called "scar producing conjunctivitis" much of the confusion of ideas and differences of opinion that now exist concerning the diagnosis of the disorder would never have arisen.

Clinically trachoma presents itself in two forms: (1) fulminating trachoma, and (2) slow trachoma.

The first is a very acute inflammation which comes on suddenly and is accompanied by the usual symptoms of a severe infection of the conjunctiva, that is, redness, swelling, lacrimation, photophobia, pain and marked thickening of the lids. This type of the disease is rare, and will be described more fully later on.

"Slow trachoma" seems to be the best term to apply to the ordinary forms of the disease. At first blush it would appear that "chronic" would be the proper adjective to use. But the condition referred to under the second heading may be either acute or chronic; hence the name "slow trachoma" will be used in this article to refer to all forms of trachoma except the fulminating type.

Slow trachoma is essentially a chronic and long drawn out disease, generally extending over a number of years. It may begin acutely, or the onset may be so insidious that the patient is not aware that there is anything wrong with the eyes. In a short time the granulations appear. These may be considered under two general headings, the papillary and the follicular.

The papillary granulations are minute structures somewhat difficult to describe. They are closely packed together, and so small that the naked eye does not ordinarily recognize them as discrete bodies, but gets the impression that the areas involved are swollen, uneven and "raw" looking on the surface. An area of papillary granulations somewhat resembles in appearance the surface of the tip of the normal tongue.

The follicular granulations are more or less rounded bodies ranging in size from the head of a pin to a small pea, and presenting considerable variation in appearance and structure. Some stand well above the surface, with a more or less pedunculated base; others are buried in the conjunctiva. They may be bright red, pinkish gray, pinkish yellow, or almost white; the latter are deeply buried. The red are quite firm; the yellowish are generally soft and gelatinous, and may be translucent. The last are known as the "sago grain" or "frog spawn" granulations.

The largest follicles are found in the culdesac, and often bleed slightly when the lid is everted. The entire conjunctiva may be studded or infiltrated with these bodies, or only a few isolated ones observed.

In a varying time, depending on the severity of the case, scar tissue begins to appear as fine white lines or irregular areas between the granulations. The production of scar tissue goes on slowly, and ultimately replaces the normal conjunctiva on practically the entire surface of the upper lid and the culdesac.

Slow trachoma occurs in various grades of acuity. A small percentage of the cases are benign, running their course with slight discomfort to the patient. Others are severe, with much inflammatory reaction and marked symptoms. All possible gradations between these two extremes are seen in the clinics.

A striking characteristic of the disease is the tendency to alternating periods of quiescence and exacerbations of the inflammatory process. The diagnostic lesions are always present, however, and can easily be detected by a careful examination of the inverted upper lid and culdesac.

In the late stages, cicatrization becomes an important feature. If the tarsal plate is involved, the shrinkage and resulting deformities of this structure cause entropion. When this is marked, the eyelashes rub against the cornea, producing ulceration and opacity. In this manner sight is involved, and ultimately vision may be lost.

"Trachoma is a veritable curse to the countries where the disease is endemic, its victims suffer for years and are usually incapacitated for years; many of them become blind."[1]

METHOD OF EXAMINING THE EYE

Before attempting to diagnose trachoma, it is imperative that the observer should become thoroughly familiar with the appearance of the conjunctiva in both health and disease, and especially the conjunctiva of the upper lid and culdesac. To explore this part of the eye it is necessary to evert the lid and also to expose the culdesac by special manipulation. The best instrument for this purpose is the ordinary wire loop cavities are sensitive to pain. "In short," he concludes, "the attempt to answer the question 'Do animals feel pain?'—which the layman answers glibly in the affirmative—is to step on a treacherous trapdoor which drops one into a hornets' nest of philosophy, psychology and biology."

88 *Gastric Cancer Simulating Malaria. C. Rovsing.—p. 861.

88. **Gastric Cancer Simulating Malaria.**—In both of the two cases described there were long paroxysms of fever, accompanied by vomiting once each time but with no other indications of digestive trouble. The first patient was a sailor, 47 years old, who began four years before to have attacks of fever, running up to 102 or 104 F. Then he vomited and the fever subsided. These attacks returned every third day for a time. Later the intervals became much longer and irregular. After two years of freedom they returned at three or four day intervals. There were never any signs of jaundice, and the bowel functioning seemed to be always regular. During the febrile periods he complained sometimes of pains in the lumbar regions and spine, but there was never hematuria or sand in the urine. The febrile attacks had been ascribed in turn to malaria, septicemia, pyelitis and cystitis, but finally, by exclusion, attention was focused on the stomach although no tumor could be felt. The functional tests and roentgenoscopy revealed stenosis of the pylorus from cancer.

The other patient was a man of 49 who began to have chills followed by fever running up to 104 F., occasionally accompanied by vomiting. These febrile attacks returned every third or fourth day but sometimes the fever kept up for four or five days at a time. He was treated with quinin and arsenic for malaria without results, and no parasites were found in the blood. By the fourth month he began to have a sensation of oppression in the epigastrium, nausea and vomiting after meals, with occult blood in the stools. The man was restored to clinical health by resection plus gastroenterostomy, and he survived for over three years before death from recurrence of the adenocarcinoma. At the first operation it was found to have involved both stomach and duodenum and some lymph glands, and it pressed against the pancreas. Rovsing has found five similar malaria-like cases of gastric cancer on record. One (Halla) was a necropsy surprise after ineffectual quinin treatment of "four day fever." In one of Hampeln's three cases the patient was dismissed from the hospital as the "malaria" had proved refractory to a course of quinin treatment, but the man returned three months later with a large tumor in the epigastrium. Necropsy confirmed the cancer but no metastases could be discovered. In his other cases the cancer was evident along with the malaria-suggesting symptoms.

The lack of symptoms of dyspepsia in the early stages in these cases is misleading. In Bühring's case (1889), there were no symptoms except those suggesting malaria to the very end; necropsy disclosed an ulcerating carcinoma and abscess in the frontal lobe. This was the only one of all the cases mentioned in which there was anything to suggest pyemia. If the fever is due to absorption of a toxin produced by the cancer, one would expect to find it continuous. More probably the toxic products generated in the stomach from the retention by the closed pylorus caused the fever when they reached a certain level. The vomiting cleared out the stomach, and there was no more trouble until this level had been reached again in the course of three or four days. This assumption is corroborated by the fact that Rovsing's first patient had one or two of the febrile attacks while convalescing from the operation, each yielding immediately to lavage of the stomach. The fever is thus not a contraindication for operative measures as the cancer itself is not directly responsible for it. The prognosis of these cases is comparatively good as is evidenced by Rovsing's first case. There had been symptoms for four years and the man has been in fine health to date since removal of the adenocarcinoma in June, 1916. It was a papillomatous tumor displaying little tendency to grow down into the depths, and was sharply circumscribed, although spreading over the lesser curvature, mostly on the rear wall and pylorus.

89 *Habitual Rectum Constipation V. T. E. H. Thaysen.—p. 1439. Commenced in No. 34, p. 1398.

89. **The Clinical Picture with Rectum Constipation.**—Thaysen, in this fifth article on habitual constipation, discusses only the clinical and roentgenologic aspects of what he calls rectum obstipation. He emphasizes that chronic constipation is not accompanied by pains unless the colon is involved, and predominantly the ascending colon. As with the latter the pains are restricted to the right iliac fossa, they are often ascribed to chronic appendicitis. Of his thirty-two patients with this "ascending constipation" the appendix had been removed on account of the persisting pains in seven. In his total series of 112 patients with chronic habitual constipation, appendicectomy had been done in eleven cases and without improving conditions in any instance. When the descending colon is involved with rectum constipation, there is usually tenderness in the left side. The pains assumed the character of colic pains only in 6 of his total 112 cases. In these 6 cases of spastic rectum constipation the different parts of the colon were involved in about the same proportions. Thaysen agrees with Pinkus that the disturbances from habitual constipation are often erroneously ascribed to gynecologic lesions.

In discussing the causes of habitual constipation, he relates that in six healthy persons repeatedly examined by rectoscopy or roentgenoscopy and digital exploration of the rectum, it was never found entirely empty. The accumulating feces could stay in it for eight hours during the day and fifteen hours including the night without inducing a desire for defecation. This suggests that the reflex inducing defecation is not started by contact of the rectal mucosa with fecal matters, as some believe. This and other facts cited seem to demonstrate that the defecation impulse proceeds from the central nervous system, started by some reflex from the digestive tract, the change to an upright position in the morning or from pylorus functioning after a meal. The physiology of the sphincters is complicated, three centers having been already found that seem to regulate it, one in the sympathetic nerve ganglia in the pelvis; one in the sacral nerves, and—in apes—one in the anterior central convolution. The mechanical effect of straining at stool is reenforced by a deep inspiration position of the diaphragm and by the contraction of the pelvic floor muscles which holds the pelvic organs up and prevents their sliding down. Weakening in any of these factors favors constipation, and also the unphysiologic high seat of the water closet.

He gives the details with the roentgen findings in 6 cases of the different types of rectum constipation, that is, retention of a considerable amount of feces in the rectum for two days without defecation. Sagging of the transverse colon does not seem to be an appreciable factor in constipation of this portion of the bowel. The distance from the umbilicus was less than 5 cm. in 2 cases of this type in men, and in 6 men and 9 women with retention any where in the colon. In 4 men and 5 women with this latter type, the distance was from 6 to 9 cm.; in 9 women it was from 10 to 12, and in one woman 13 cm. One of his tables giving the details of 74 cases of rectum constipation shows that there were no pains in 20 of 29 pure cases; no pains in one of 8 cases of the same, plus retention in the ascending colon; in one of 3 cases of rectum constipation plus retention in the transverse colon, and none in 17 among 34 cases of rectum constipation plus retention in various portions of the colon from cecum to sigmoid flexure. With pure constipation in the ascending colon, pains were pronounced in 19 of 23 cases. In none of his cases of rectum constipation did he ever find the rectal sphincter abnormally contracted, not even in his 6 cases of spastic rectum constipation, but he noted an unmistakable spasm of the sphincter in 3 nervous patients with no tendency to constipation. Sphincter spasm can generally be traced to an anal fistula or hemorrhoidal tumor.

the ordinary inflammations, the structure of the conjunctiva in any given area is practically uniform, that is, it is a homogeneous tissue; but in trachoma the structures are permanently changed. Scar tissue is formed, and it is deposited in irregular and more or less sharply defined patches. Between these patches are areas of highly vascular inflammatory tissue or normal conjunctiva (Figs. 3 and 4).

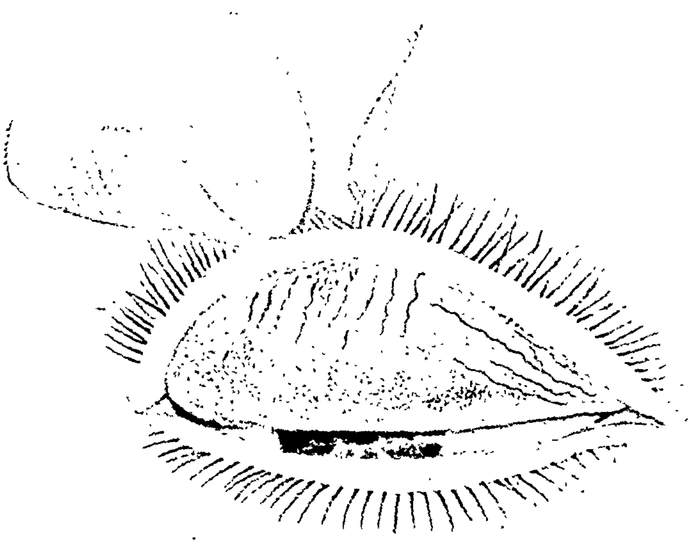

Fig. 3.—Upper lid of right eye. This illustration shows the appearance of a case of slow trachoma before proper pressure has been made with the eye turner. The lid is roughened and the adventitious blood vessels can be noticed running across the outer third of the tarsal plate. It is impossible, however, to make out any scar tissue when the lid is manipulated in this fashion. This should be contrasted with the same lid after the proper pressure has been applied, as shown in Figure 4.

When pressure is made from beneath this ordinarily invisible scar tissue, it becomes white much more easily than the other elements of the conjunctiva; hence this maneuver enables us to detect it when it is present in very small amounts, that is, in the early stages of the disease. In well marked cases of long standing (Figs. 5 and 6), the scar tissue is at once apparent even to the most casual observer on simply everting the lid; but in recent or very mild cases, the scar tissue may be present in so slight an amount as not to be apparent unless the lid is manipulated as described above. The whole conjunctiva in such patients is more or less inflamed and swollen, and the small areas of scar tissue are deep down and obscured by the inflammatory changes (Fig. 3).

The lower lids are inspected by pulling them down with the index finger and having the patient look up, meantime moving the finger slightly from side to side to roll out all parts of the lower fornix.

It cannot be positively determined that any suspected individual is free from this disease until both lids of each eye have been carefully examined in the manner just described. Certain changes on the tarsal plate are always present in trachoma; but they may be so slight that only an expert can detect them, and the upper culdesac should invariably be examined by all ordinary observers.

The specific causative agent of trachoma has not as yet been discovered, although a tremendous amount of research work along this line has been carried out.

Prowazek has described certain cell inclusions that are frequently found in smears from trachomatous eyes that have been stained by Giemsa's method. Similar inclusions are found, however, in the pus from inclusion blennorrhea and sometimes in the genital discharges of men and women suffering from acute inflammation of these parts. Reference must also be made to Lindner's "initial bodies." These are coccilike bodies seen in the cavities of the protoplasm of the epithelial cells. They apparently multiply, and are believed by some investigators to be living organisms. Whatever the ultimate decision may be regarding the true nature of these cell inclusions, the subject may be dismissed for the present with the statement that the finding of these bodies is so inconstant as to render the making of smears and their microscopic examination of but little practical assistance in the clinical diagnosis.

Despite occasional assertions to the contrary, there is no doubt that trachoma is transmissible from one person to another. Fulminating trachoma spreads rapidly among the crowded occupants of a vessel's steerage, as has been amply demonstrated several times on vessels arriving at Ellis Island.

The virus of slow trachoma is not as virulent as the other variety, and some individuals undoubtedly possess a high degree of resistance to it. This explains the fact that several members of a family may escape although all the rest have the disease. Deliberate and accidental inoculations in human eyes have not always resulted in producing the disease. Cases are also occasionally encountered in which but one eye is involved.

The results of the attempts to inoculate apes and other animals with trachoma are inconclusive. Certain workers claim to have done so; but as the condi-

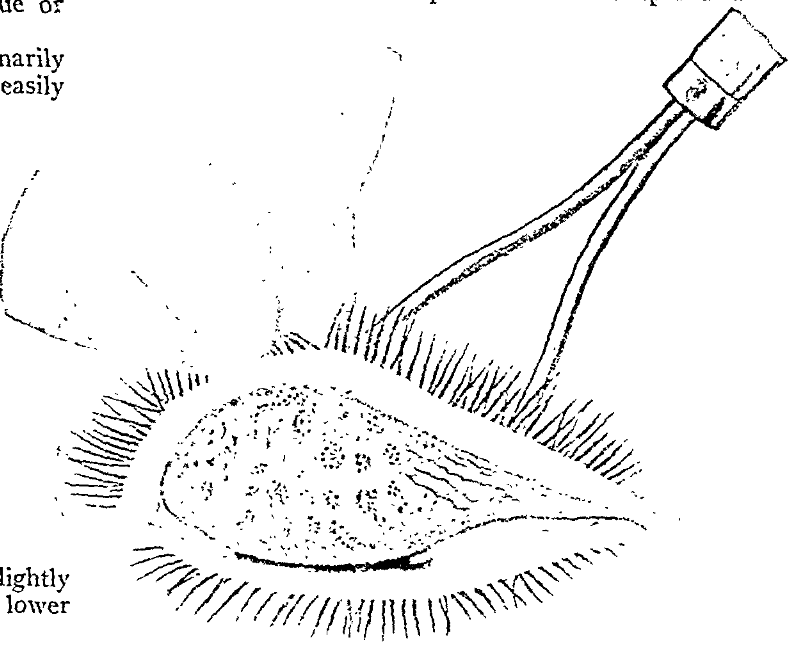

Fig. 4.—This is the same lid shown in Figure 3, but the glove buttoner has been manipulated so as to make the lid more or less anemic and bring out the scar tissue. Note the areas of papillary granulations surrounded by the bands of white scar tissue. This method of using the turner to make the lid anemic requires some practice, but is of extreme importance in detecting scar tissue in its early stages.

tion produced disappeared spontaneously in a few months without the formation of scar tissue, the identity of the disease produced in these animals with human trachoma has not been satisfactorily proved. The fact that inclusion bodies were found in the scrapings from the ape's eyes cannot be considered as confirmatory until the nature of these inclusions is definitely settled.

Surgeon C. H. Lavinder and I made numerous attempts to inoculate *Rhesus* monkeys and baboons with material obtained in cases of slow trachoma of the acute type. The experiments were carried on for several months, but the results were uniformly negative.

THE GRANULATIONS

Papillary Granulations.—The gross appearance of these granulations has already been described. According to MacCallan:

> The papillary growths are caused by an increase in the surface area of the hypertrophic conjunctiva. The latter is thrown into folds between which correspondingly deep clefts are formed; then on cross section the folds appear as papillary ridges. The connective tissue forming the papillae is covered with a very much thickened epithelium which of course is continued on into the depressions. These depressions have thus in microscopic cross section the appearance of narrow canals lined with epithelium and were accordingly regarded at one time as tubular glands; and hence the formation of new glands was alleged to occur in trachoma.
>
> Papillary hypertrophy as above described is not pathognomonic of trachoma; it is found in any condition of long continued irritation of the conjunctiva such as results from ectropion, spring catarrh and chronic conjunctivitis.

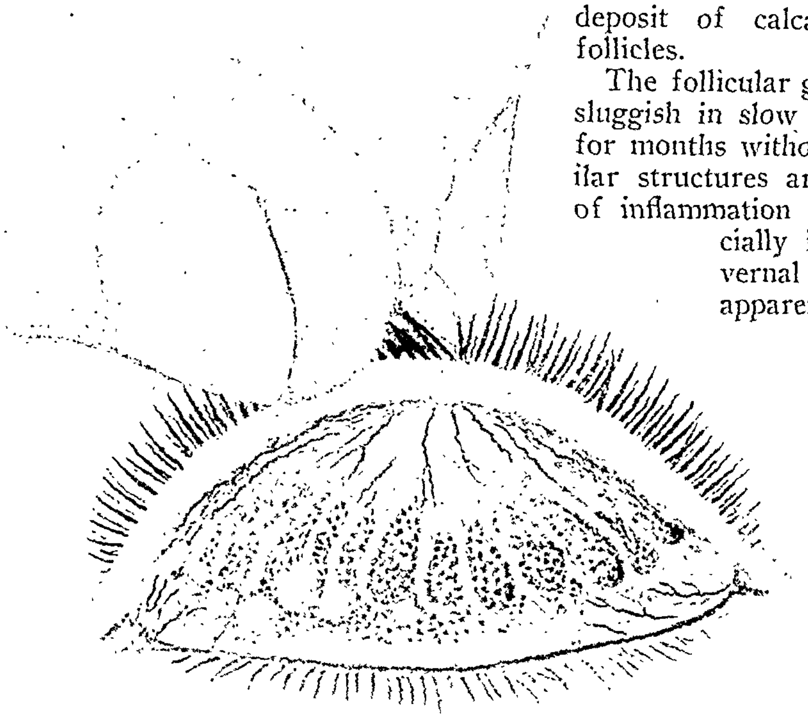

Fig. 5.—Upper lid of right eye. A *typical case of slow trachoma of several years'* standing. The islands of papillary granulations separated by vertical narrow lines of scar tissue are well marked. There are five *large gelatinous follicles* at the lower border of the tarsal plate. Note that the culdesac has *been replaced almost* entirely by *scar tissue.* The normal vertical vessels in the culdesac have disappeared, and a few adventitious vessels running in an oblique direction can be seen in the nasal side of the culdesac. There still remains some normal *conjunctiva in the* upper part of the lid.

Follicular Granulations.—These are the larger granulations ranging in size from a pinhead to a small pea. The largest ones are found in the culdesac. There are three quite distinct types, the red follicles which are the ordinary kind, the yellow gelatinous follicles, and the buried white follicles. All three varieties may be found in the same eye.

The firm red follicle is a very common lesion in all forms of trachoma (Fig. 9). These follicles may be simply poorly defined eminences in the conjunctiva, or well marked rounded bodies. The whole upper lid may be a mass of these new formations (Fig. 11), but it is more usual to find them along the lower border of the tarsal plate (Fig. 9).

The gelatinous gr[illegible]tion are grayish yellow bodies, so[illegible] si[illegible] uently translucent. Large [illegible] icles are often found in the culdesac. They may bleed slightly when the lid is everted. These are the so-called "sago grain" or "frog spawn" granulations (Figs. 5 and 10).

Sometimes they fuse together, forming an area of intermingled gelatinous and scar tissue. This condition is known as Stellwag's brawny edema, or the gelatinous trachoma of Stellwag. It is especially common in the culdesac, the conjunctiva in this region being very much thickened, light bluish gray, and composed of fairly smooth scar tissue infiltrated with gelatinous material (Fig. 6).

The pure white follicle is found in the tarsal region, deeply buried in the conjunctiva, showing through as a small whitish spot or point (Fig. 9). Granulations of this description are not very common; when present they are generally found in the acute type of slow trachoma. As they are very rare in the ordinary inflammations of the conjunctiva, they may be rated as having some diagnostic importance. Care must be taken, however, not to mistake the small yellow bodies, often seen in normal eyes and due to a deposit of calcareous matter, for real follicles.

The follicular granulations are extremely sluggish in slow trachoma, and may exist for months without apparent change. Similar structures are seen in various forms of inflammation of the conjunctiva, especially in follicular catarrh, and vernal conjunctivitis. They are apparently not an essential lesion of the disease, but merely the reaction of the lymphoid elements of the conjunctiva to certain types of prolonged irritation.

The microscopic pathology of trachoma is in a somewhat chaotic state, considerable difference of opinion existing on many important points. It has been commonly taught that the follicles either ruptured and became organized, or became organized without rupture, and that in this way the scar tissue was produced. The objection to this view is the fact that the follicles produced by other forms of inflammation, especially follicular conjunctivitis, histologically resemble very closely the follicles in trachoma, and that these structures disappear without the formation of scar tissue, or at least without producing enough scar tissue to be detected clinically. The organization of the follicles either with or without rupture does not seem sufficient to explain the amount of cicatrization found in trachoma.

From a clinical standpoint there is good reason to believe that when the virus of trachoma attacks an eye, it ultimately invades the deeper structures of the conjunctiva and frequently in old cases the tarsal plate. The organism proliferates in these deeper structures, and gives rise to products that cause a rapid hyperplasia not only of the lymphoid elements but also of the connective tissue cells. The proliferation and organization of the fibrous elements of the conjunctiva produce the scar tissue which ultimately crowds out and entirely replaces the normal elements of the conjunctiva. The process of cicatrization, then, as pointed out by Fuchs,[2] is somewhat analogous to interstitial hepatitis, and *not* at all similar to the healing of an ulcer by scar tissue. As long as there is any lymphoid tissue left, the infection remains in it indefinitely. The virus does not exist in the scar tissue after the latter becomes fully organized.

Mayou asserts that by the use of certain plasma stains it is possible to distinguish histologically between many of the follicles of trachoma and those found in follicular conjunctivitis. He believes that:

> The granules found in trachoma are follicular formation plus trachomatous infection, the follicles being simply an effort on the part of the tissue to produce mononuclear cells, and becoming secondarily infected with trachoma. Although, indeed, as a general rule a considerable number of them seem to be infected even in the early states, . . . yet follicles can be found in trachomatous conjunctivitis which are evidently not infected with trachoma.

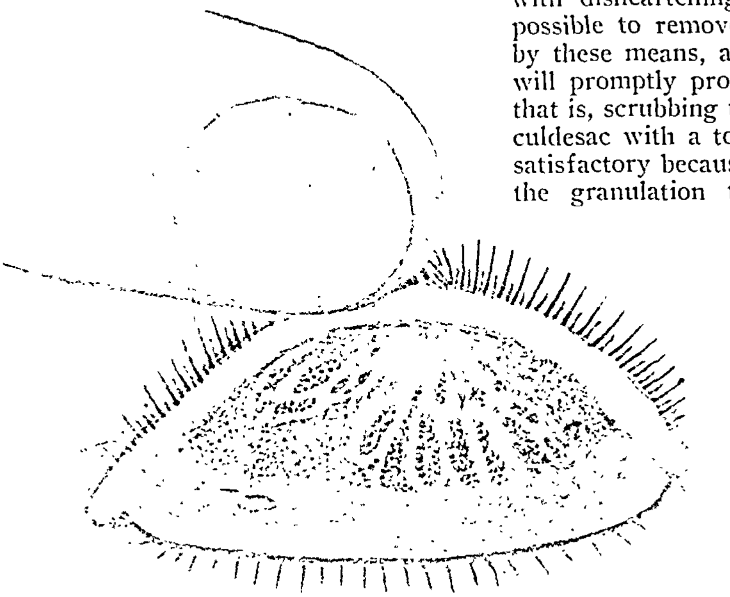

Fig. 6.—Upper lid of left eye. An old case of slow trachoma. Cicatrization is well marked. There remain, however, a few areas of papillary granulations near the center of the lid. The culdesac is completely filled up with a mass of poorly defined gelatinous granulations representing a typical case of Stellwag's brawny edema. The disease has existed for about six years.

This view coincides closely with the clinical course of the disease, and is probably correct. The student should clearly understand that the follicular granulations are not an essential or diagnostic feature of trachoma, but should be considered as a complication. They do, however, afford a lurking place for the virus where it proliferates or may remain latent for months.

In trachomatous eyes there is first the formation of ordinary follicles which are due to the irritation; and later on the virus invades these structures so that at first they are ordinary follicles and later on specific.

Rupture of the follicle may take place either from a thinning of the epithelium overlying it, owing to pressure from beneath, or from an interference with the blood supply by the scar tissue, causing necrosis.

The follicles are semisolid; hence, when rupture occurs, a part of the contents may escape, but not all. Septic infection of the ruptured follicle, however, is likely to occur, and the secondary inflammatory process ensuing may cause a temporary increase in size. Ultimately the follicle is destroyed by the combined action of the pyogenic organisms and the trachoma virus.

Undoubtedly some of the follicles, especially the smaller ones and those deeply buried in the conjunctiva, disappear by some process of absorption or atrophy.

Cases under treatment have been examined daily for a period of a year and a half without the rupture of any of the follicles being observed, and hence it will be apparent that the formation and rupture of the follicle is not a progressive pathologic process occurring in a more or less definite period of time.

It was formerly the custom to attempt to destroy these bodies by expression. In nontrachomatous cases, mechanical destruction of the follicles is followed by a disappearance of the condition in a comparatively short length of time. Some of the popularity of this method of treatment was probably due to cures produced in cases in which a mistake had been made in the diagnosis. Expression in true trachoma may hasten the disappearance of the larger follicular granulations, but it has no effect on the papillary granulations which are always present. A striking characteristic of trachomatous tissue is its ability to regenerate after partial destruction. The granulations may be curetted, excised, expressed or cauterized, and yet they return with disheartening persistence. It is impossible to remove all the lymphoid tissue by these means, and any trace that is left will promptly proliferate again. Grattage, that is, scrubbing the surface of the lid and culdesac with a tooth brush, is much more satisfactory because this operation removes the granulation tissue quite thoroughly; and the mercuric chlorid solution used on the brush is likely to sterilize what little remains. Grattage, however, cannot produce a cure when the tarsal plate is invaded by the trachomatous process, the infected tissue here being buried deep in the cartilage where the bristles of the brush cannot possibly reach it. Grattage followed some weeks afterward by removal of the tarsal plate is the procedure advocated by certain specialists for cases of this description.

The visible granulations in trachoma are generally limited to the under surfaces of the lids and culdesac, similar formations being very rarely seen on the bulbar conjunctiva. However, Mayou[3] determined that on section the bulbar conjunctiva does show changes, and at the corneal limbus certain inflammatory and degenerative areas may be noted. When properly stained and sectioned, on microscopic examination these areas are found to contain typical trachomatous follicles. Occasionally small pits or sunken scars may be observed just outside the limbus due to the cicatrization of these areas.[4]

SCAR TISSUE

In severe cases the scar tissue begins in the culdesac and spreads most rapidly in that region. In mild cases it may first of all be detected in the inner canthus at the junction of the tarsal plate with the culdesac, and careful search should always be made in this locality in doubtful cases. On the tarsal plate it generally extends upward in narrow bands toward the edge of the lid, with islands of exuberant lymphoid tissue in between (Fig. 5). A large stellate area in the middle of the tarsus is not unusual.

---

[2] Fuchs, H. E.: Text Book of Ophthalmology, Ed. 5.

[3] Mayou, H. S.: The Changes Produced by Inflammation in the Conjunctiva, Hunterian Lecture, 1906.

[4] MacCallan, A. F.: Trachoma and Its Complications in Egypt, Cambridge, 1913.

In the majority of patients the extreme outer and inner borders of the plate are the last to become cicatrized. The culdesac always becomes completely converted into scar tissue long before the process is completed on the upper lid. When completely organized, the scar tissue is pure white, smooth, and somewhat glistening. Usually it forms in islands which slowly spread; but very rarely the formation takes place simultaneously and at a uniform rate over the entire tarsal conjunctiva. In mild cases the process goes on very slowly, and it may be years before the lids are completely cicatrized.

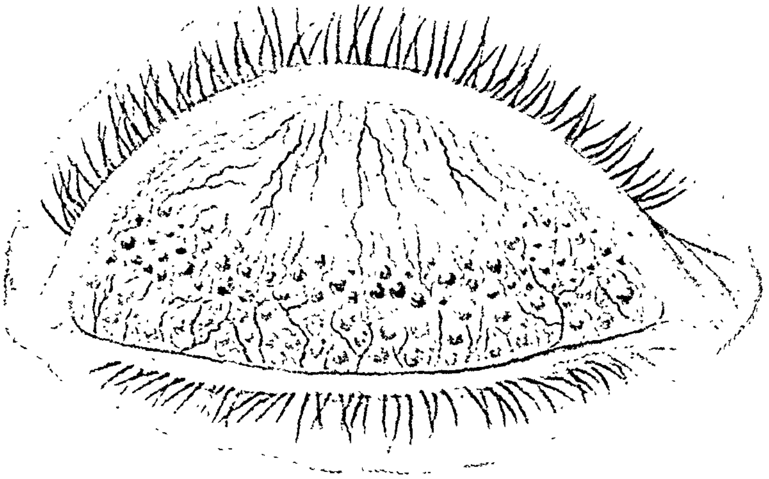

Fig. 7.—Follicular conjunctivitis, upper lid of right eye. The culdesac and the lower portion of the tarsal plate are studded with a large number of follicles. These follicles are fairly uniform in size, almost perfect hemispheres, and they appear to spring from the surface of the conjunctiva and are not buried in that structure. This form of follicular conjunctivitis is not so common as that shown in Figure 8. The diagnosis from trachoma in cases of this type is made by the fact that the conjunctiva is not thickened, that the normal blood supply is maintained, the vessels of which can plainly be seen running vertically upward in the culdesac; also by the size, appearance and superficial position of the follicles. It should be observed that there is no thickening in the conjunctiva of the culdesac, that structure being normal in the spaces between the granulations.

Patients are occasionally encountered with a narrow band of scar tissue running horizontally across the culdesac. The strip is so even in width and sharply demarked as to appear as if made by a surgical operation. The tarsal conjunctiva is somewhat thickened, but not characteristic of trachoma. MacCallan[4] believes that scars of this description are produced by a former attack of gonorrheal conjunctivitis, and this opinion is probably correct.

The lower lids for some reason recover much more promptly than the upper, and it is not always easy to decide whether scar tissue is present. For this reason an examination of the lower lid alone often affords but little information in slow trachoma. Many well marked and severe cases will be found in which the lower lids present absolutely no pathologic changes to the naked eye.

In fulminating trachoma, however, the lower lid is diagnostic in the early stages.

PANNUS

In all cases of trachoma, pannus is generally present. This statement is not to be construed as meaning that a leash of large blood vessels will be found running across the cornea; but that on close inspection, with a hand lens if necessary, a fringe of very fine, almost invisible vessels invading the cornea from the conjunctiva can be detected. They are generally most marked in the upper and lower segments, but may extend completely around the corneal limbus. A more or less opaque gelatinous membrane is apt to follow the vessels onto the cornea.

Pannus is now considered as trachoma of the cornea and to be due to an invasion of that structure by the specific inflammation.

A temporary invasion of the cornea by fine vessels as described above may be encountered in a number of acute inflammations of both the cornea and the conjunctiva. According to MacCallan,[4] the permanent pannus of trachoma may be distinguished from that due to ulcers of the cornea and a secondary variety produced by interstitial keratitis, by the following points: When due to an ulcer, the vessels are larger and are localized to one part of the cornea. The pannus produced by interstitial keratitis arises from the deeper blood vessels of the sclera, and the vessels seen on the cornea cannot be followed up and proved to be continuous with those of the conjunctiva; while in trachoma it can be determined that the fine vessels seen on the cornea are branches from the conjunctival blood supply.

Pannus of a moderate degree frequently clears up, leaving but slight evidence. When present it is merely an evidence of irritation of the cornea and the response of that tissue to inflammation, and should be considered as a corroborative and not a positive sign of trachoma.

CORNEA

In old neglected cases or those that have been very severe, it is common to find corneal opacities with extensive pannus. Many such eyes are seen among the Egyptians, Syrians, Indians and some of the mountaineers of our own country.

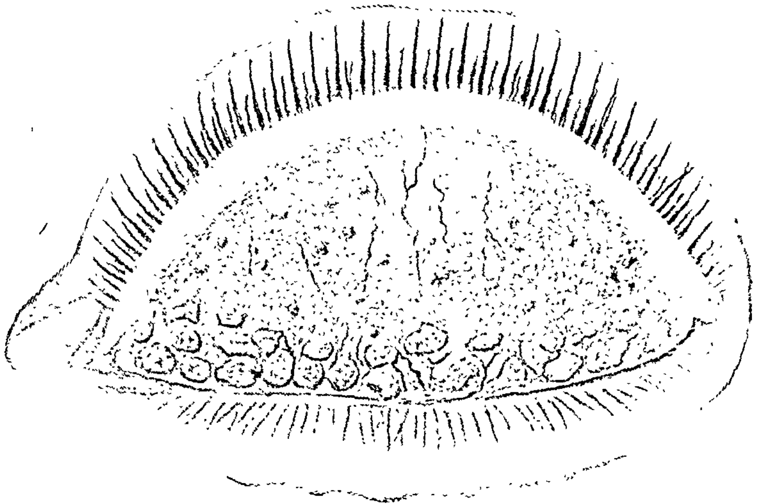

Fig. 8.—Typical case of follicular conjunctivitis, upper lid of left eye. In this patient the culdesac is filled up with a number of irregularly shaped, light colored follicles. The conjunctiva over the tarsal plate is somewhat roughened and thickened, and contains a few scattered small lymphoid follicles. Here there is a hypertrophy of the lymphoid elements of the conjunctiva with chronic conjunctivitis. The diagnosis between cases of this type and trachoma is sometimes extremely difficult. Lids of this description are very frequently found in schoolchildren, and often cause the examiner much embarrassment in making diagnosis. Careful observation will sh , that the norm blood vessels can still be seen here a culdesac; als that there are areas of more or less between t large follicles in that region. In su tissue can detected; neither is there any true tra ne examinat of the throat and nose in these patic ays show there is hypertrophy of the adenoid lities, such enlarged tonsils or adenoids.

Ulceration of the cornea its f two causes:

1. The trachomatous inflammation attacks the tissue of the cornea itself, or some other form of infection gains lodgment in a trachomatous eye, causing the ulcer by the usual pathologic changes.

2. The contraction of the eyelid, especially the deformity of the tarsal plate, produces trichiasis, and the inverted lashes rub on and irritate the cornea. The last seems to be the commonest cause of opacity of the cornea.

The older teaching, that the roughness of the upper lid due to the follicles was responsible for the damaged cornea, cannot be true. Hundreds of cases with eyelids fairly studded with follicles are seen in which the cornea is clear and uninjured; hence some other cause for the corneal lesions must be sought.

The invasion of the cornea by the disease itself and the trichiasis are the more likely causes. Some weight must also be given to the interference with the circulation of this structure due to the constant pressure of a deformed lid.

DEFORMITIES OF THE LIDS

Some degree of ptosis is present in almost all cases of slow trachoma of long standing, and it is especially marked in the fulminating type of the disease, the lids being greatly swollen.

In old cases the shrinkage of the scar tissue produces various deformities, and the lower edge of the lid is apt to present a wavy line instead of the normal curve with the convexity downward (Fig. 12). Such eyes have a "droopy" look, very significant to the trained observer.

In severe cases the inflammatory process does not stop at the conjunctiva, but also invades the tarsal cartilages where no ordinary applications can reach it. Scar tissue is produced here as elsewhere, and the plate may be twisted and pulled entirely out of shape by the resulting cicatrization. Entropion with trichiasis, as mentioned above, is the usual result and the most serious. In slow trachoma the disease may exist for many years before these changes become evident, and in some mild cases they never appear at all.

The conditions which have just been described are the usual lesions of trachoma. Among the rarer sequelae of severe cases of the disease should be mentioned exerosis conjunctivae, posterior symblepharon and ectropion of the lower lid.

DISCHARGE

In all trachoma there is more or less secretion; but the disease is so often complicated with other conjunctivitis that the nature of the discharge is of little importance and of no help in making the diagnosis.

CLASSIFICATION OF TRACHOMA

Various classifications based on clinical characteristics have been proposed by the different writers on trachoma. Some of them are rather complicated, and none altogether satisfactory. A common plan has been to describe the papillary, follicular and mixed forms, according to the type of granulations which predominated. As papillary granulations are always present as long as the trachoma is active, there can be no such condition as a simple "follicular" form in contradistinction to a "mixed" type, and either the "follicular" or the "mixed" subdivision should be omitted, for the terms in this instance are synonymous.

If some clinical classification of slow trachoma is desired to secure brevity of description, the term "papillary" might be properly applied to those cases of trachoma in which no follicles can be detected by the naked eye, and "follicular" to those in which, in addition to the papillary granulations, definite follicles are present. It must be clearly understood, however, that this is a clinical classification only; because if the papillary cases are examined microscopically, true trachoma follicles will be found in the conjunctiva, but they are too small or too deeply buried to be seen on inspection.

The gelatinous trachoma of Stellwag has already been mentioned. In it there is a fusing together and gelatinous infiltration of the follicles which is more commonly found in the culdesac.

STAGES OF TRACHOMA

When the formation of scar tissue has advanced sufficiently so that it is easily observed in the conjunctiva, the eye is described as being in the beginning stage of cicatrization.

As the process proceeds and the areas of scar tissue equal or exceed the other parts, the case is referred to as being in the advanced stage of cicatrization.

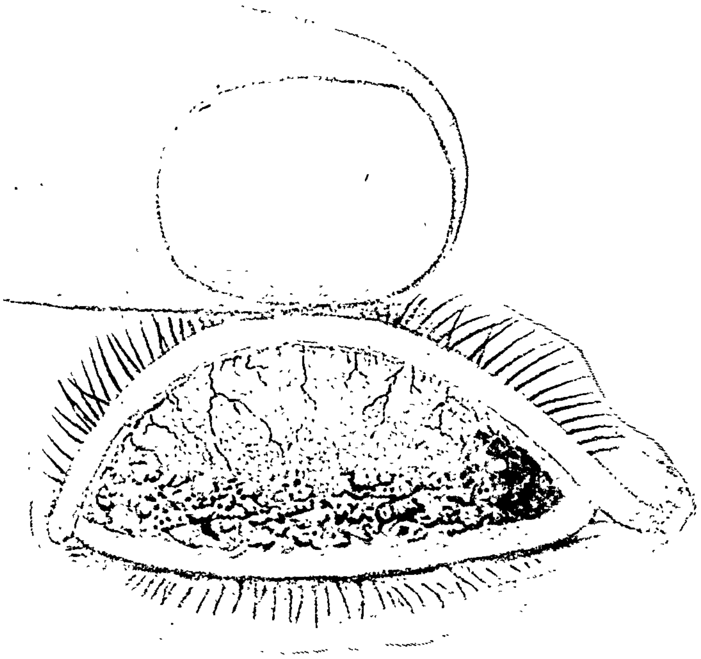

Fig. 9.—Recent case of slow trachoma, upper lid of right eye. The lower part of the culdesac of this eye is completely converted into scar tissue. On the lower part of the tarsal plate there is an area of poorly defined, deep red, partially buried granulations. Higher up still are a number of deeply buried small white granulations. Careful examination with the eye turner showed beginning scar tissue between the granulations over the tarsal plate. The deep buried white granulations are strongly significant of trachoma. Note the thickening of the culdesac and the absence of any visible blood vessels in that locality. This case should be studied in conjunction with Figure 8. The diagnosis of trachoma is made on the scar tissue and deeply buried white granulations, and the absence of the normal blood supply. There was also marked pannus in this case.

"Cicatricial lids" is the term applied to the eyes when the trachomatous tissue has been completely replaced by firm, smooth, white scar tissue. This is nature's only method of effecting a cure.

RELATION TO SURROUNDINGS, RACE AND AGE

Trachoma flourishes chiefly among the overcrowded, underfed, overworked, and those living in bad hygienic surroundings generally. No locality or race is exempt, however, and occasionally cases are found among the well-to-do and those whose method of life is above reproach from a sanitary standpoint. The age incidence is extensive. I have seen a well marked case in a child under 2, and I have a patient under treatment now who contracted the disease after 63.

FULMINATING TRACHOMA

Fulminating trachoma is an acute and severe inflammation of the conjunctiva. The onset is abrupt, the upper and lower lids becoming affected practically simultaneously.

The palpebral conjunctiva is intensely red, very edematous, and much thickened. It has not the velvety appearance of a severe case of acute conjunctivitis, but is more coarsely granular; and while it may not present typical discrete follicles, its surface is markedly irregular and uneven like a piece of broken granite (Fig. 11). The ocular conjunctiva is always more or less involved, sometimes very severely; but it does not usually present any diagnostic symptoms other than those of a very intense reaction. The conjunctiva of the lower lid presents the same appearance of broken granite and appears to be superabundant, being thrown up into folds or ridges. Discrete and definite follicles may also be present in this locality.

While the lids are always very much thickened from the start in this type of the disease, the time for the appearance of the characteristic unevenness or follicles varies considerably. It may be delayed for seven or eight days, generally, however, appearing early or about the fourth day.

There is photophobia, blepharospasm, and a profuse watery discharge sometimes mucopurulent. The cornea often becomes involved either from an interference of its blood supply by the edematous and inflamed ocular conjunctiva, or by being attacked directly by the infection itself. Ulceration and infiltration may follow with widespread destruction to the corneal substance and subsequent opacities.

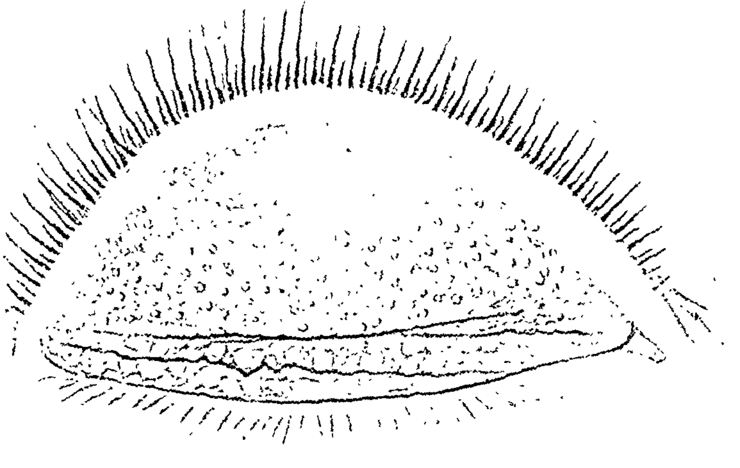

Fig. 10.—Slow trachoma of some months' standing, upper lid of right eye. The culdesac here is filled with a mass of poorly defined, semigelatinous granulations of a pinkish salmon color. Deep cracks can be observed between the granulations which are arranged more or less roughly in rows. The conjunctiva of the tarsal plate is much thickened, very rough, and shows numerous small granulations which can be best detected at the nasal and temporal extremities. No blood vessels are visible anywhere in the eye. No scar tissue could be detected by the most careful search. It is difficult to make a positive diagnosis of trachoma in eyes of this type at the first examination, although the appearance is strongly suggestive of that disease. Patients presenting this appearance should be given treatment for several weeks before a definite and positive opinion is given as to the nature of the disease.

Fulminating trachoma is much more easily transmitted from one person to another than slow trachoma. Generally both eyes are affected, but in rare instances only one eye is involved. The period of incubation has not been definitely determined, but appears to be within eight days.

Fulminating trachoma is a rare disease; in fact, its existence has been denied by some authorities; but on a number of occasions, cases of this type of the disorder have appeared among the crowded occupants of the same steerage compartment of vessels arriving at Ellis Island.

Differential Diagnosis.—Fulminating trachoma must be diagnosed in the early stages from severe phlyctenular conjunctivitis and from acute infections of that membrane by various micro-organisms, especially the gonococcus and the diplobacillus of Morax-Axenfeld. Unless one of these specific organisms is demonstrable in a properly stained smear made from the discharge, the diagnosis may be impossible for a few days. As soon, however, as the characteristic lymphoid enlargement has appeared, the true nature of the disease may be determined. The upper lids in severe simple conjunctivitis and phlyctenular conjunctivitis may present a roughened granular appearance which is apt to be confusing; but in these conditions the lower lids never present the same exuberance of the conjunctiva with the lymphoid follicles so well marked or so prominent as they are in fulminating trachoma. The characteristic phlyctenules in phlyctenular conjunctivitis will also assist in separating that disease. It must also be remembered that there may be an attack of phlyctenular conjunctivitis in an eye already infected with trachoma or a severe attack of acute conjunctivitis in conjunction with follicular catarrh, in which case the diagnosis is practically impossible until the acute complication has subsided. The shortest period in which scar tissue has been demonstrable in these cases by me was six weeks after the beginning of the attack. This, however, is probably unusual, scar tissue not appearing in the ordinary case of the fulminating type until several months have elapsed.

In fulminating trachoma the ocular conjunctiva is always intensely inflamed. This symptom is of material assistance in separating the disease from slow trachoma which is undergoing an acute exacerbation.

COMPLICATIONS OF TRACHOMA

An eye that is already the seat of a trachomatous inflammation may have added thereto any of the other infections to which the conjunctiva and cornea are liable. These conditions are known as "complicated trachoma," and are quite common. The trachomatous process does not protect the eye, as far as is known, from any other kind of inflammation; but, on the other hand, it appears to predispose it to certain forms. A gonorrheal infection is very common with trachoma among the Egyptians, and spring catarrh is frequently complicated by trachoma in localities on which both diseases are common.

The addition of any other infection to a trachomatous eye causes a swelling, redness and discharge which may make the diagnosis for the time being extremely difficult or impossible. Most of these complications, however, can be subdued or overcome by appropriate treatment, maintained for a sufficient length of time, and then the true condition can be definitely determined. The clinical appearance of complicated trachoma, therefore, is that of the original disease plus the symptoms of the added infection. The rule in all such cases is appropriate treatment until the complication has subsided.

DIFFERENTIAL DIAGNOSIS OF SLOW TRACHOMA

The important diagnostic symptoms of trachoma are scar tissue, papillary granulations and trachoma follicles. The most important of these is the scar tissue. It may not be present in the early stage, but sooner or later it is bound to appear. The method of searching for and demonstrating the presence of scar tissue has already been fully explained. It must be remembered in this connection, however, that scars are formed in the conjunctiva by burns from lime or other escharotics, and also by certain infections that cause sufficient inflammatory reaction to produce sloughing or ulceration of that membrane. The narrow strip running horizontally across the culdesac caused by gonorrhea has already been described. Considerable scarring also is the result occasionally of severe cases of smallpox. The scars formed by burns or ulcers, however, differ materially in appearance from those of trachoma, as they are sharply demarked and the conjunctiva is not infiltrated in the irregular manner that is found in that disease.

FOLLICULAR CONJUNCTIVITIS

There are two types of follicular conjunctivitis. The variety illustrated in Figure 7 is unusual. This form may be described as a true folliculosis without an accompanying conjunctivitis. The follicles are small, in color match that part of the conjunctiva in which they are found, glassy in appearance, very uniform in size, sharply demarked from the surrounding tissues, and appear to spring from the surface of the conjunctiva rather than to be embedded in that structure. In these cases the conjunctiva is not inflamed or thickened, but maintains its normal appearance between the follicles; and, what is of the utmost importance, the blood vessels show the same arrangement and stand out as clearly as they do in the normal eye.

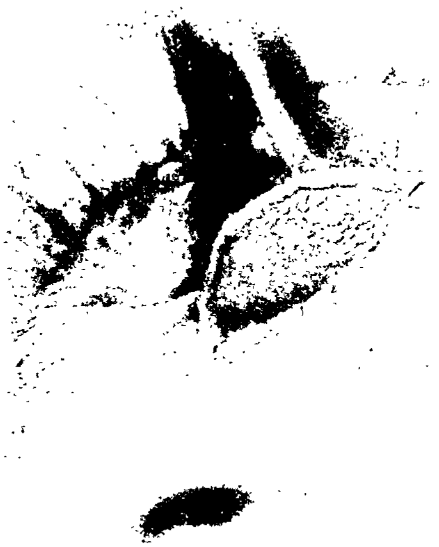

Fig. 11.—Fulminating trachoma of several months' standing. The upper lid is everted and fastened in position on the rubber eye plate by means of two sutures. The patient is under ether preparatory to the grattage operation. A good part of the culdesac can be seen, especially in the nasal half of the eye. Note the numerous granulations, which have been described under the section on fulminating trachoma as having a characteristic appearance something similar to broken granite.

The other type of follicular conjunctivitis is that shown in Figure 8. Here there are numerous follicles in addition to a low grade chronic conjunctivitis. The follicles are irregular in shape and size. The largest are found chiefly in the culdesac or on the lower border of the tarsal plate. They are not so sharply demarked as in the preceding type, and there is more or less thickening and roughening of the conjunctiva between the follicles, although not nearly so much as is found in a true trachoma. The blood supply, while somewhat obscured by the slight inflammatory reaction present, is nevertheless normal, and can be made out on proper examination.

It is this form of follicular conjunctivitis that has caused the greatest confusion in the diagnosis of trachoma, especially among schoolchildren. The process appears to be merely a part of a general hyperplasia of the lymphoid tissue throughout the entire body, for in such cases there are often found adenoids and enlarged tonsils; and the period of life in which this disease occurs corresponds to that in which there seems to be a marked tendency for all the lymphoid tissue to proliferate on slight stimulation. The local irritation in this instance may be due to dust, foul air, gases, and even possibly eye strain.

When the characteristic scar tissue can be made out by the proper manipulation of the eye turner, it is easy to rule out follicular conjunctivitis. In recent cases the diagnosis must be made on two things: (1) the condition of the conjunctiva of the culdesac and lower one third of the tarsal plate (everted lid), and (2) the blood supply of the culdesac.

In the early stages of trachoma, the fornical conjunctiva of the upper lid is always more swollen, inflamed and rough than in follicular conjunctivitis, and no areas of normal tissue can be seen in this region or over the lower third of the tarsal plate.

No visible blood vessels can be detected in the culdesac in the beginning stages of trachoma, as the inflammatory changes obscure them. In follicular conjunctivitis the vessels may be almost hidden or considerably distorted by the follicles; but if any vessels are observed running in a *vertical or approximately vertical direction* across the culdesac, it is safe to exclude trachoma (Fig. 8).

Occasionally it may be necessary to treat the eyes for a few days with sedative and slightly astringent remedies in order to overcome a temporary inflammation before giving a positive opinion as to the nature of the case.

VERNAL CATARRH AND OTHER DISEASES

In this disease the conjunctiva of the tarsus is the seat of a number of papillae which are broader and flatter than those in trachoma. The new growths are crowded closely together, resembling somewhat a cobblestone pavement, and are frequently covered by a bluish white film. In addition to the palpebral lesions, there also may be new formations around the limbus of the cornea in the shape of uneven, hard, gelatinous masses. The symptoms of vernal catarrh are much worse in the spring and summer than in the winter, and the history of the case often will assist in the diagnosis. The characteristic lesions are present throughout the year, but the signs of acute inflammation, that is, the redness, photophobia and lacrimation, are much ameliorated during the winter.

Some cases show involvement only of the tarsal plate, with no symptoms around the limbus of the cornea. In others the cornea is the only part affected. The secretion is generally scant, but when properly stained shows a large number of eosinophil cells.

The diagnosis from trachoma is made on the history; the appearance of the granulations, which are larger, flatter, paler and more closely packed together than in trachoma; the bluish white membrane when present, and the large number of eosinophil cells found in the discharge.

The commoner inflammatory conditions of the conjunctiva likely to be mistaken for trachoma have been described in detail. Other diseases that present clinically somewhat similar lesions to trachoma and may on rare occasions have to be diagnosed from that disorder are tuberculosis of the conjunctiva, syphilis of the conjunctiva, nodules around foreign bodies and Parinaud's conjunctivitis.

Tuberculosis of the conjunctiva appears as small grayish nodules on the tarsal surface with occasional ulcers. There is apt to be swelling of the glands in front of the ear. The bacillus may be found in sections of the involved tissue or by inoculation of the material into guinea-pigs. As a general thing, the disease attacks but one eye, and is not very painful.

Parinaud's conjunctivitis is a rare disease involving in most instances but one eye. It is characterized by the formation of follicles and sometimes ulcers in the conjunctiva. A marked feature is the systemic condition, the patient at the onset having fever, chills and enlargement of the preauricular gland, which frequently goes on to abscess formation. The entire parotid region may be swollen and tender. Sometimes the retromaxillary and cervical glands are also involved. In addition to the follicles, the eyelids are swollen and hard, and the culdesac is often very red and edematous. The chills, fever and involvement of the glands differentiate this form of conjunctivitis from trachoma.

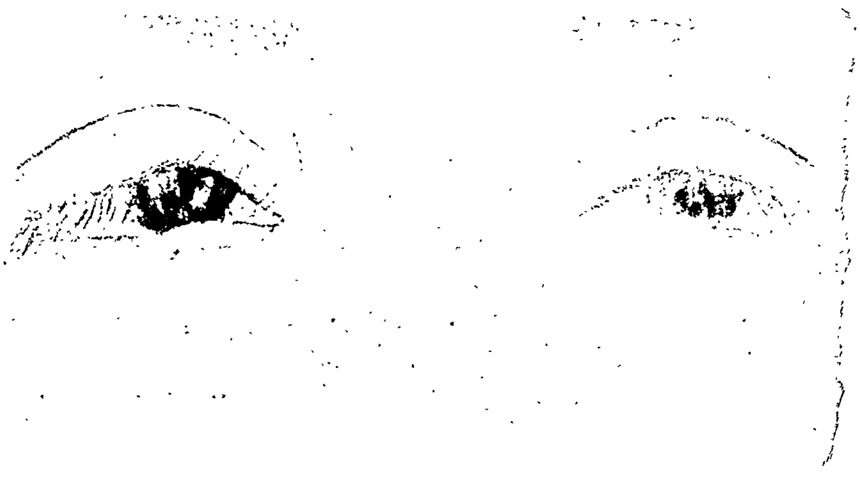

Fig. 12.—Thickening and deformity of the lids produced by a long standing case of trachoma. Note that the outer two thirds of the right upper lid presents a curve which is concaved downward, while the normal eye has its concavity upward.

WHEN IS TRACHOMA CURED?

On this point there is a great diversity of opinion. Patients attending clinics are often discharged as cured when acute inflammatory symptoms have subsided and there is no discharge. Such cases, however, almost invariably relapse sooner or later, and the mere cessation of secretion and the acute subjective symptoms should not be taken as proof of recovery from the disease. When an eye has become infected with the trachoma virus, it is liable to a recurrence as long as any normal conjunctiva, or any lymphoid tissue in the conjunctiva remains. The infection lingers in the granulations apparently indefinitely, and some trifling local irritation or constitutional disorder may cause it to spring into renewed activity at any time, and thus produce an acute exacerbation of the disease.

A case can never be said to be certainly cured until all the conjunctiva of the upper lids has become completely replaced by smooth, white, avascular, fibrous scar tissue, and the lower lids are free from any evidences of the disease. A vascular scar tissue cannot be infected by the virus of trachoma. In treating trachoma with silver nitrate, copper sulphate, grattage, expression, etc., the cicatricial process is simply hastened by chemical and mechanical destruction of the normal and abnormal tissue of the lids and the irritation resulting from these various measures.

THE ILLUSTRATIONS

It is extremely difficult to get good illustrations of trachoma, as there are several things which interfere with accurate reproductions of the conjunctiva. In order to show the diseased area to the artist it is necessary to evert the upper lid. This procedure is more or less uncomfortable to the patient, and the lid cannot be maintained in this position for a very long period of time. The appearance and color of the conjunctiva itself changes from moment to moment on account of the varying blood supply and the irritation produced by the eversion.

Long training is essential in order that the observer should be able to grasp and appreciate quickly the very minute pathologic changes by which the different inflammatory diseases of the conjunctiva are diagnosed. It is extremely important that in all cases the culdesac should be carefully brought into view by proper manipulation of the tip of the glove buttoner. In most of the illustrations the entire culdesac is shown, but it should be remembered that in the actual work the examiner can see only one part of the culdesac at a time. Hence, in actual practice, it is impossible to get as complete a view of the diseased structures as is shown in the pictures.

The black and white drawings were made by Artist Leonard H. Wilder of the United States Hygienic Laboratory, after paintings made by S. Shimatori of actual cases occurring in immigrants at the United States Immigrant Hospital at Ellis Island, New York. They are as correct reproductions of the conditions seen as the artists could portray.

The illustrations were made three times the original size in order that the finer details on which so much depends in the diagnosis of trachoma might not be lost in the process of reproduction. It is advised that they be studied, first of all with a minus lens of sufficient strength to bring them down to the size of a normal eyelid, in order to get the general effect, and afterward with the naked eye for the purpose of observing the finer details.

U. S. Immigration Station.

City Celebrates New Water Supply.—October 12, New York began its celebration of the completion of the Catskill aqueduct. This aqueduct is approximately 120 miles long and its construction has covered a period of ten years. It has been completed, however, within contract time, without a labor strike, and its cost has been kept within the original estimate. The opportunity offered by the completion of this great work for teaching important civic lessons is not being neglected. The great influence of water supply on the public health is being impressed in the school celebrations and public meetings. For this purpose a pamphlet has been prepared by the department of health at the request of the Mayor's Catskill Aqueduct Celebration Committee which is being used as a text for compositions on this subject.

CESAREAN SECTION SCARS

A HISTOLOGIC STUDY OF FOUR SPECIMENS *

ALFRED BAKER SPALDING, M.D.
SAN FRANCISCO

Originally the indications for cesarean section were limited, because delivery by laparotomy without suturing the uterus, although occasionally successful, nearly always resulted in death from hemorrhage. Suturing the uterus to prevent death from hemorrhage was followed so frequently by peritonitis that Jorg,[1] in 1806, suggested a method of extraperitoneal cesarean section which was in fact successfully performed by Ritgen,[1] in 1821. Rarely repeated cesarean section was successful in preantiseptic days, in cases in which the adhesions were sufficiently extensive to wall off the peritoneal cavity. Porro, in 1876, devised his operation for removing the uterus and suturing the cervix into the laparotomy wound. While the Porro operation greatly reduced the mortality of cesarean section, the removal of the uterus was considered to be too radical a procedure to permit of any marked increase in the list of indications for cesarean section.

But when Sänger, in 1882, described his well known conservative operation, the immediate results were found to be so good in regard to fetal and maternal mortality that the original small list of indications for cesarean section was greatly increased.

It has been estimated that today cesarean section is resorted to about once in each 200 confinements, which probably is a fairly conservative statement. In hospitals and clinics the ratio may at times be even greater. For instance, at the Stanford Women's Clinic, eighteen cesarean sections have been performed in the last 2,060 consecutive confinements, or, on an average, one cesarean section for each 115 confinements.

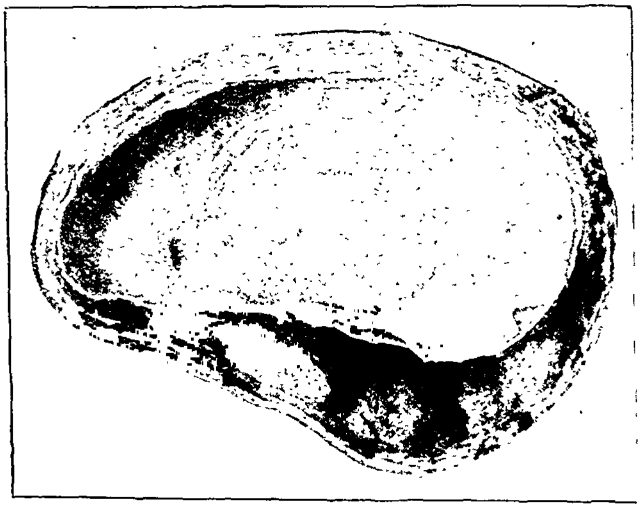

Fig. 1.—Cross section of the pregnant uterus at 18 weeks; wall outside placenta, 6 mm.; placenta, 22 mm.; wall under placenta, 5 mm.

The subsequent history of this large class of cesareanized women is a matter not only of scientific interest, but also of sociologic concern. The possibility of sterility, of abortions, of almost certain sterility after the second cesarean section, as well as future rupture of the uterus, must be thought of before resorting to the comparatively simple expedient of abdominal cesarean section, when possibly some other obstetric operation, such as pubiotomy or vaginal hysterotomy, might do as well and might give to the patient a simpler obstetric future.

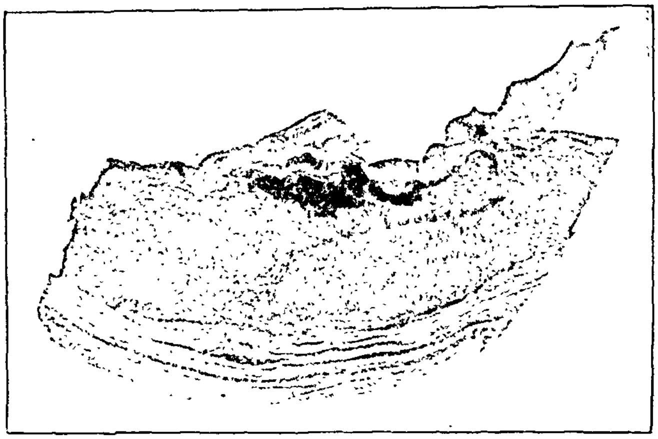

Fig. 2.—Placenta and uterine wall in first stage of labor: wall outside of placenta from 7 to 9 mm.; placenta, 22 mm.; wall under placenta, 6 mm.

After cesarean section, many patients have fever with more or less inflammation of the endometrium; many remain sterile after one cesarean section, either from choice, or because the operator has sterilized them; many abort after cesarean section spontaneously or are aborted through fear of future difficulties, while a relatively small number are repeatedly cesareanized. Some patients, after the classic Sänger or Fritsch operation, occasionally have a rupture of the uterus in succeeding pregnancies. Von Leuwin,[2] in 1904, and Singer,[3] in 1908, wrote valuable theses on this subject.

Weber,[4] in 1910, called attention to the fact that in the Münchner Frauenklinik the percentage of uterine ruptures had increased from one in 1,476 labors previous to 1899, to one in 697 labors since 1899. He attributes this increase in the number of ruptures to injuries to the uterus caused by previous operations, particularly to injuries caused by curettage in the puerperal period. Of twenty-eight ruptures during this operative period, one was through an old cesarean scar.

Krukenberg,[5] in 1886, reported twelve cases of rupture in twenty-four pregnancies after cesarean section.

Later Sänger stated that rupture had only rarely occurred after his operation, and that when it had occurred, it was because of poor technic on the part of the operator. As a result, the early reports of rupture dealt exclusively with cases in which some other operator performed the original cesarean section. However, Wyss,[6] in 1912, collected from the literature forty-three reports of rupture occurring

since 1895, and Palmer Findley[7] has recently increased this list to a total of sixty-three. In addition to these, the following ruptures may be found reported in the literature; Banby and Gilles,[8] Cristalli,[9] Baisch,[10] Mabbott,[11] Wyder,[12] Weber,[4] Cameron[13] (two cases), Lüsebrink,[14] Bell,[15] and Rongy[16] (two cases).

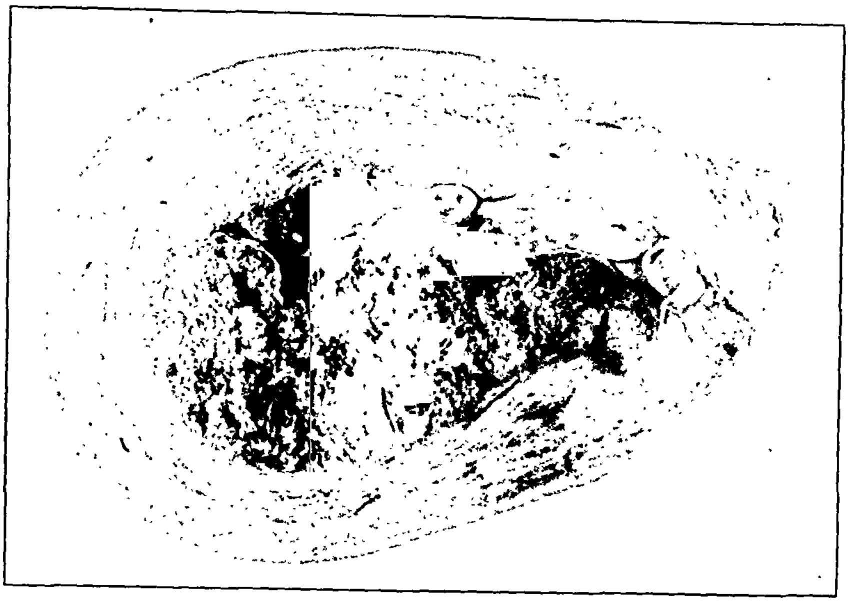

Fig. 3.—Sagittal section of the uterus and placenta in the third stage of labor: wall outside placenta, 28 mm.; placenta, 45 mm.; wall under placenta, 18 mm.

The frequency of rupture after cesarean section can at best be only roughly estimated. Couvelaire,[17] quoting from von Leuwin, made the statement, which is found so often in the literature, that rupture occurs in about 2 per cent. of pregnancies after cesarean section. As a matter of fact, von Leuwin stated in his thesis that 77 patients who became pregnant after cesarean section and were not treated by repeated cesarean section gave the following history: there were 8 spontaneous, and 3 artificial abortions, 6 ruptures of the uterus (dans la cicatrice ou ailleurs [in the cicatrix or elsewhere]), 22 prematurely induced labors, 21 spontaneous labors at term, 3 symphysiotomies, 3 embryotomies, three extractions with forceps, and 2 versions with extraction. In the paragraph following, he states that of a total of 194 pregnancies, including 117 repeated cesareans with the 77 previously mentioned, there were noted 24 defective scars. Of these, 4 were completely ruptured, 14 were defective to the peritoneal coat, and 6 were partly defective. From the first paragraph, one might conclude that there were 6 ruptures in 66 cases (by excluding the abortions) or more than 9 per cent. of ruptures. Or, from the second paragraph, one could agree with Couvelaire that the number of ruptures were four in 194, or about 2 per cent. However, the percentage (12) of defective scars agrees very well with the findings recently reported by Harrar.[18] Of 50 cases of repeated cesarean section at the New York Lying-In Hospital, there were noted 8, or 16 per cent. of defective scars.

Of forty cesarean sections in private practice or in my clinic, only one patient to my knowledge has had spontaneous labor later. This patient, reported by Breitstein,[19] had one normal spontaneous labor, and then the uterus ruptured spontaneously in the last month of the next pregnancy.

Laparotomy was performed by Breitstein twenty-four hours after the occurrence of the rupture, because the patient complained so little as to obscure the diagnosis. The uterus was found ruptured on the anterior wall in the old cesarean scar. The placenta lay outside on the anterior wall of the uterus. Around the edge of the rupture, there was an intense leukocytic infiltration in the decidua. The upper part of the rent was covered by the decidua vera. Around the central and lower parts, the decidua had the appearance of the serotina. The muscle in the upper part toward the peritoneum was normal.

Of the seventy-five reported cases in the literature, in only eighteen are there pathologic reports of the histology of the scars. Of these, two authors (Ekstein[20] and Breitstein[19]) report syncytial elements in the scars with good muscle healing; seven (Schick,[21] Couvelaire,[17] Dahlmann,[22] two cases, Fischer,[23] two cases, and Wyss[6]) report finding

placental elements in poorly healed scars. Two (Prüsmann[24] and Jolly[25]) found decidual islands in the scar as the sole cause of rupture, and Wolf[26] reports the same finding associated with poor muscle healing. In addition, many state that the decidua approaches, as one would expect, to the peritoneum over the surface of poorly healed scars. Of the eighteen reports, thirteen record poor wound healing as the chief cause of rupture. Clinically, vomiting in late pregnancy, cervix bags, bougies, hydramnios, overtime fetus, ulcerating ventral hernia, long labor without engagement, manual extraction of the placenta, abdominal fixation of the uterus, version and pituitary solution have been noted to explain the rupture, while several cases are reported without strain of any kind and with few of the usual symptoms of uterine rupture. Some have been found unexpectedly at operation. Couvelaire thought the rupture in his case occurred to one side of the old scar through the uterine muscle, which agrees with the clinical reports by Krukenberg[5] and Davis,[27] and with the opinion of Mason and Williams,[28] based on animal experiments.

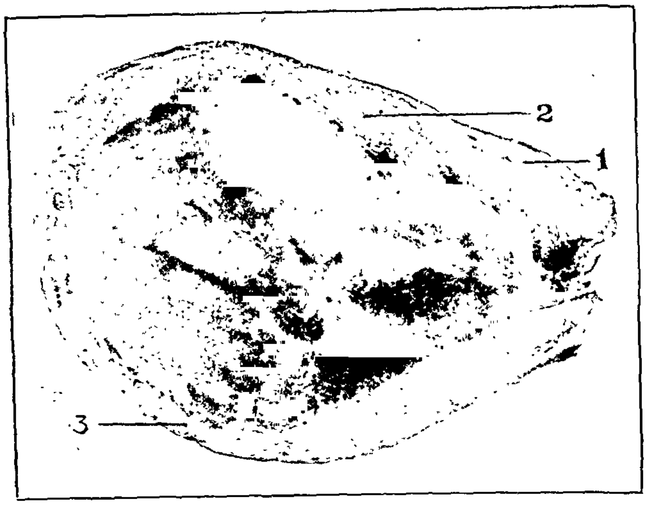

Fig. 5.—Sagittal section of the uterus and placenta with rupture of the uterus at site of old cesarean section scar: *1*, thickened lower uterine segment, 21 mm.; *2*, placenta, 15 mm. thick; *3*, point of rupture, old scar, 2 mm.

From 1895 to 1900, when the classic Sänger operation was in universal vogue, only three cases of rupture were reported. From 1900 to 1911, during the time when many resorted to the transverse fundus incision of Fritsch, forty cases of rupture were reported. Wyss condemned all operations except the Sänger operation, and believed the ruptures were due to infection and to poor technic. Several have mentioned that in the fundus, the postpartum contractions may loosen the sutures, and result in poor wound healing. German literature is full of good results following the extraperitoneal operation. Lichtenstein,[29] Reinhardt,[30] Scheffzek,[31] Rubeska[32] and Mayer[33] have reported labors lasting from five to sixty-eight hours without rupture, while Unterberger[34] states that no case has yet been reported of rupture following the extraperitoneal operation. However, Wolf[26] reports a case of rupture after a transperitoneal operation, and Labhardt[35] encountered rupture in a case of placenta praevia following delivery by Dührssens incisions in a previous confinement. In Findley's list of sixty-three ruptures, ten make mention of the placental site at the time of the first cesarean section. Of these, eight incisions were made into the placenta. Twenty-two mention the placental site at the time of rupture. Of these, nineteen find the placental site in or near the rupture.

It has frequently been suggested that the incising of the placental site might lead to imperfect healing of the regenerating endometrium, as well as the possibility of the developing placental elements weakening the scar, as happens in some cases of ectopic pregnancy. Both these facts could account for the better prognosis following extraperitoneal cesarean section.

While it is plausible that the placental elements might lead to poor healing of the wound in cases in which the incision is into the placental site, there is hardly sufficient evidence available to uphold the idea that the syncytium will attack sound scar tissue any more than it does sound uterine tissue. To verify this, we studied the uterus in a girl who died when she was eighteen weeks pregnant, and found that the wall was 6 mm. thick, the placenta 22 mm. in thickness, while the thickness of the wall underlying the placenta was 5 mm. (Fig. 1). The histology of the muscle wall differed from cesarean scars in being of looser texture, containing many more small blood vessels, less fibrous tissue, and no fibrin, except in the

decidua, where the chorionic elements formed attachment. The wall of the uterus in a woman dying in the first stage of labor (Fig. 2) measured from 7 to 9 mm. in thickness, except at the placental site, where it measured 6 mm.

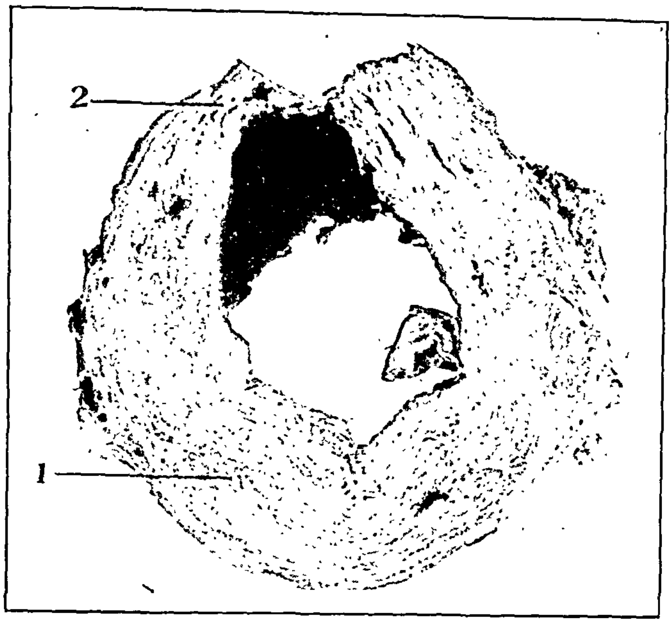

Fig. 7.—Cross section of uterus showing fresh cesarean incision and old cesarean section scar; good healing: *1,* muscle wall, 26 mm.; *2,* old scar, 9 mm.

From a Porro-cesarean section case (Fig. 3), the thickness of the uterine wall in the third stage of labor was found to be 28 mm. outside the placental site, and 18 mm. beneath the placenta. The thickness of the wall in the nonpregnant state was observed to be about 17 mm.

From these observations, it appears that the normal uterine muscle wall is somewhat thinner beneath the placenta than it is at other places, and it might be argued that a sound cesarean scar over the placenta would be thinned in the same proportion; but there is no histologic evidence to prove that the normal uterine wall or the well healed scar is weakened by the invasion of syncytium, such as occurs in mole pregnancy and in ectopic gestation.

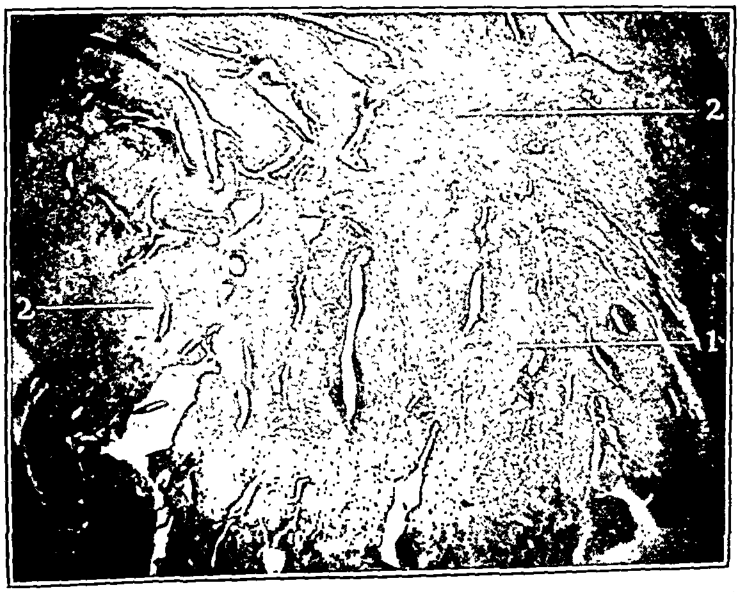

Fig. 8.—Low power photograph of old scar in Figure 7: *1,* normal muscle tissue; *2,* scar shows fibrous tissue; few muscle cells.

Histologically, the strong well healed scar is practically no different from normal uterine tissue. Defective scars, however, contain more fibrous tissue, fewer blood vessels, less muscle tissue, less elastic tissue, and when in contact with the placenta, more fibrin deposits. The placenta may actually protect a weak scar by acting as a splint to cover the wall defect. On the other hand, a small retroplacental hemorrhage might rupture the uterus. The most plausible reason to explain actual rupture of the uterus seems to rest on mechanical principles. Given a weak scar defective near to the peritoneal coat, a small water wedge of liquor amnii (Fig. 4) will cause the uterus to rupture, on the same principle that it causes the cervix to open. Scars in the lower uterine segment are protected more than scars in the fundus from this action. Using a cervix bag which increases the intra-uterine pressure will cause added danger. In the third stage of labor, retroperitoneal hemorrhage might well cause rupture.

In this connection I desire to report the following histologic findings of cesarean section scars:

REPORT OF CASES

Case 1.—*History.*—A white woman, aged 32, was examined in consultation at an outside hospital, Sept. 13, 1916. The patient was in her third pregnancy. In 1914, the cervix had been amputated. The first labor occurred five years ago and it was a high forceps delivery, the child being delivered dead. The second labor took place three years ago, at which time a cesarean section was performed by a general surgeon; no fever occurred during the puerperium. The present labor was due Sept. 2, 1916, and the three measurements of the pelvis which had been taken were normal. The promontory was high and was palpated with difficulty; the pubic angle was acute. Labor began September 12 at 1 a. m. with strong pains. The position was breech, and at 1 p. m., September 13, the membranes ruptured and meconium was noted in the liquor amnii. The pains stopped, and 0.5 c.c. of pituitary solution was given, causing hard pains. At 2:10 p. m., under ether, the attending physician attempted to deliver the child by breech extraction, but could not extract the head. At this point the history is vague, but the result was that the body was severed, leaving the head in utero. At 7 p. m. the patient was moribund, with rapid pulse and continuous, although moderate, bleeding from the vagina. As there were no craniotomy instruments to be had in the hospital, and as it seemed probable that the uterus containing the fetal head was both ruptured and septic, an immediate hysterectomy was done. There were many adhesions on the anterior surface of the uterus, but no rupture of the cesarean scar appeared to

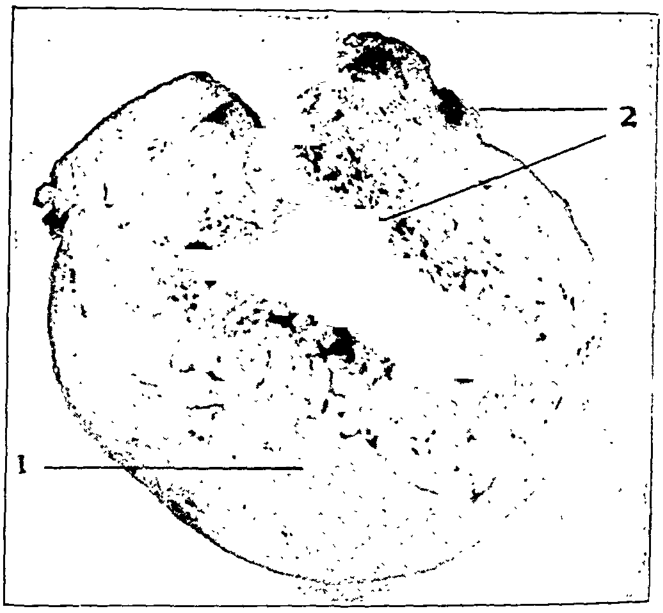

Fig. 9.—Cross section of uterus showing fresh cesarean incision and old cesarean section scar, good healing: *1,* muscle wall, 55 mm.; *2,* old scar, 28 mm.

be present in spite of the severe twenty-four hour labor and the use of pituitary solution. The patient died shortly after operation. After a delay of several weeks, I was able to obtain the specimen of the uterus for study. Unfortunately, the fixation of the large specimen was poor.

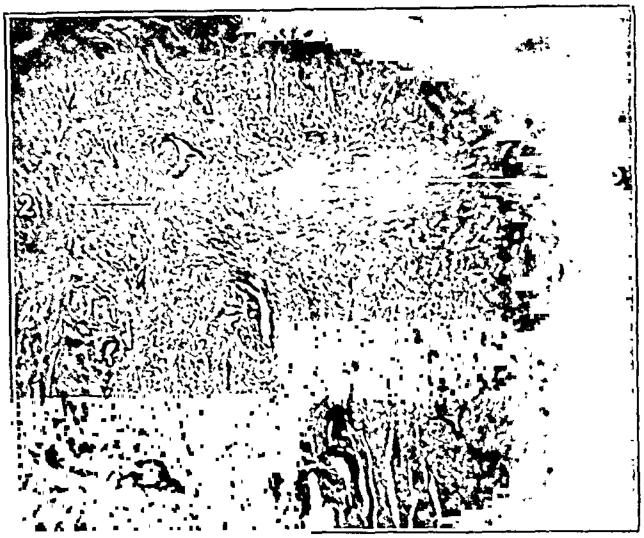

Fig. 10.—Low power photograph of old scar in Figure 9: *1*, normal muscle tissue; *2*, *2*, scar is practically the same as the normal uterine wall except for slight deposit of fibrin.

Pathology.—The specimen consisted of the uterus above the internal os (containing a large fetal head), right ovary and tube. There were many adhesions over the anterior and left lateral surfaces of the uterus. The uterus measured 18 cm. transversely at the line of tubal insertion; 14 cm. anteroposteriorly, and had a length of 22 cm. On the posterior wall of the uterus on the fundus just above the line of insertion of the fallopian tubes, there was an irregular white scar, 2.5 cm. wide and about 8 cm. long, which ran transversely and a little downward from left to right. The scar seemed to be held together and protected in a splintlike manner by the attached placenta beneath. The placenta had a very large attachment over the anterior wall, fundus, and part of the posterior wall of the uterus. The wall of the uterus was thickened to 22 mm. in the lower part of the uterus, extending posteriorly to a distance of 15 cm. (just to the old uterine scar), and 10 cm. on the anterior wall above the internal os. Beneath these points over the fundus, the wall was thinned to 5 mm., except at the site of the scar, which is 2 mm. The attached placenta was 15 mm. thick (Fig. 5).

Microscopic Examination.—Sections of the uterine wall revealed fairly distinct layers of normal muscle tissue with a thin layer of decidua. The placenta was in situ, and the villi were normal. At one point, the muscle tissue thinned out to a hairlike line, beneath which there was a layer of hemorrhage which overlay the proliferating villi. In places, the thin peritoneal coat was ruptured. This was at the site of the old cesarean incision. Beyond this, the muscle wall again thickened. In the scar, distinct muscle bundles were lacking and had been replaced with wavy fibrillar connective tissue (Fig. 6).

Case 2.—*History.*—A white woman, aged 20, had a simple, flat contracted pelvis, the true conjugate measuring 7 cm. Labor was due Sept. 5, 1913, but the pains began August 23. It was a breech presentation, and the fundus measured 30 cm. above the symphysis, the presenting part being above the brim. The patient preferred the cesarean section to pubiotomy. At the operation, the incision was made in the midline below the umbilicus, and the uterine incisions in the midline on the anterior wall of the uterus into the placenta. The incision in the uterus was closed with two layers of interrupted chromic catgut (avoiding decidua), and one layer of continuous sutures. Lembert chromic suture was used in the peritoneum. Convalescence was normal, and no fever developed. Jan. 11, 1916, this patient returned to the clinic in labor with a vertex presentation. The fundus measured 34 cm., and the presenting part was above the brim. After nine hours of good labor pains without engagement of the presenting part, a Porro-cesarean section was done, as the patient requested sterilization.

The uterine incision was made in the midline on the anterior wall of the uterus into the placenta; the old incision was not visible. Convalescence was normal, and there was no fever.

Pathology.—The uterus measured 14 by 10 by 10 cm. There were no adhesions. The old scar was to the left of the recent incision and the wall was thinner and somewhat puckered. The wall of the uterus outside the old scar was 26 mm., while the scar measured 9 mm. (Fig. 7).

Microscopic Examination.—The scar showed much fibrous tissue with practically no muscle cells. There were a few blood vessels in the scar, but no decidual or syncytial elements were present. With Weigert's stain, the normal elastic elements seen in the muscle tissue were lacking in the scar. The scar appeared strong, although fibrous and shrunken (Fig. 8).

Case 3.—*History.*—A white woman, aged 25, had a flat, rachitic pelvis. The true conjugate measured 9 cm., and between the tubera ischii, 7.5 cm. The patient was delivered by cesarean section in the Cooper College Clinic, April 12, 1912. Interrupted catgut sutures and continuous Lembert sutures in the peritoneum were used. Convalescence was normal except for a fever of 101.6 F. on the day of operation. Nov. 16, 1916,

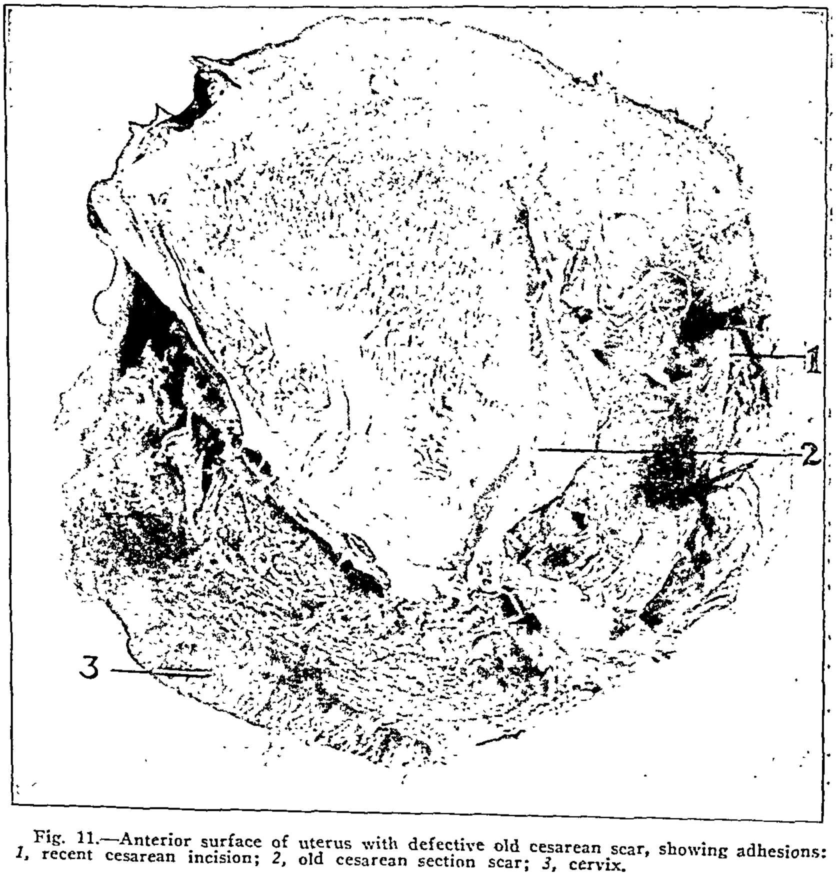

Fig. 11.—Anterior surface of uterus with defective old cesarean scar, showing adhesions: *1*, recent cesarean incision; *2*, old cesarean section scar; *3*, cervix.

this patient reported to the Stanford Clinic in labor. The fundus measured 34 cm. above the symphysis. It was a breech presentation, but no engagement had as yet occurred, although the membranes were ruptured. After two hours of pains, the patient was delivered by Porro-cesarean section, as she requested sterilization, and the membranes had been ruptured since labor began. Incision was made through the right rectus below the umbilicus. There were adhesions between the uterus and the anterior wall. The uterine incision was made on the anterior wall. The placenta was located on the posterior wall of the uterus. Convalescence was normal, except for temperature of 101 F. on the first day and the eleventh day.

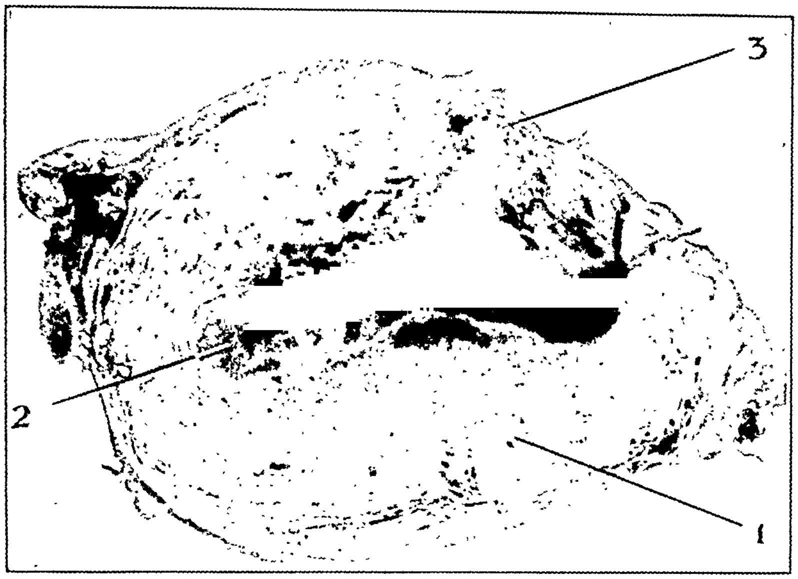

Fig. 12.—Sagittal section of the uterus shown in Figure 11, with defective old cesarean section scar: *1,* muscle wall, 38 mm.; *2,* decidua, 6 mm.; *3,* defective scar, 1.5 mm.

Pathology.—The uterus measured 11.5 by 11 by 9 cm. There were no adhesions except at the line of the old scar, which was 4.5 cm. long. The scar on the upper part of the anterior surface was in the midline, and the uterine wall in its thickest part was 55 mm. The endometrium was thick and shaggy; the scar was 28 mm. thick. The placenta was inserted on the posterior wall (Fig. 9).

Microscopic Examination.—The scar was the same as the other muscle tissue, except for slight fibrin changes and slight depression in the mucous membrane. It was stained with the van Gieson stain, hematoxylin and eosin stain and with the Weigert stain for elastic tissue. In part the muscle fibers were not quite so compact, but the amount of elastic tissue was about normal (Fig. 11).

Case 4.—*History.*—A white woman, aged 26, pregnant for the second time, came to the Stanford Women's Clinic, Sept. 7, 1916, in the seventh month of pregnancy. Twenty-one months previously she had had cesarean section at term performed by a surgeon in Sacramento, after twenty-four hours of labor. The pelvis measured 24, 26, 29.5, 21 and 20 cm. The laparotomy scar extended from the ensiform around the left side of the umbilicus to a point midway between the umbilicus and symphysis. A ventral hernia occupied the line of the old incision. No history of the convalescence was available.

A Porro-cesarean section with repair of the hernia was performed, Dec. 5, 1916, at the request of the patient that she be sterilized. There were very few light adhesions encountered. The uterine incision was in the anterior wall to the left of the old scar, and the placenta was on the anterior wall of the uterus. Convalescence was normal except for a temperature of 101 F. on the day of operation.

Pathology.—The uterus, consisting of body and fundus to the internal os, measured 15 by 13 by 8 cm. The old scar was blue, 8 cm. long, 1.5 mm. thick and 15 mm. wide. The wall of the uterus opposite the old scar was 38 mm. thick, and the mucous membrane was 6 mm. thick (Fig. 12).

Microscopic Examination.—Sections of the scar revealed a thin layer of peritoneal tissue with attached adhesions. Beneath this layer, there was a very thin layer of muscle tissue, but no fibrous tissue. There was a thin layer of decidua containing much fibrin, and attached to this was the placenta. On either side of the scar, there was much fibrin deposit enclosing decidua, fetal cells and muscle fibers. There were many masses of syncytium to be seen some distance away from the scar between the muscle bundles. There was about the same amount of elastic tissue in the scar as in the muscle tissue on either side. This was mostly associated with small blood vessels (Fig. 13).

CONCLUSIONS

1. It seems justifiable to conclude that more than 10 per cent. of cesarean section scars are defective.

2. The chief cause for the defect seems to lie in imperfect healing of the endometrium.

3. In case the incision is into the placental site, there may be imperfect healing due to the degeneration of decidua serotina, or the scar may be weakened by the inclusion of decidual tissue in the muscle wall.

4. There is not much evidence to uphold the view that the syncytium attacks the well healed scar, although two such cases have been reported.

5. The placenta is frequently found overlying the weakened scar in cases of rupture. This may produce rupture from retroplacental hemorrhage, or may act as a splint to support the weakened scar.

6. Of seventy-five reported cases, all but one were ruptures in the upper part of the uterus. From this it seems that the extraperitoneal cesarean section carries with it a better prognosis than the classic abdominal operation.

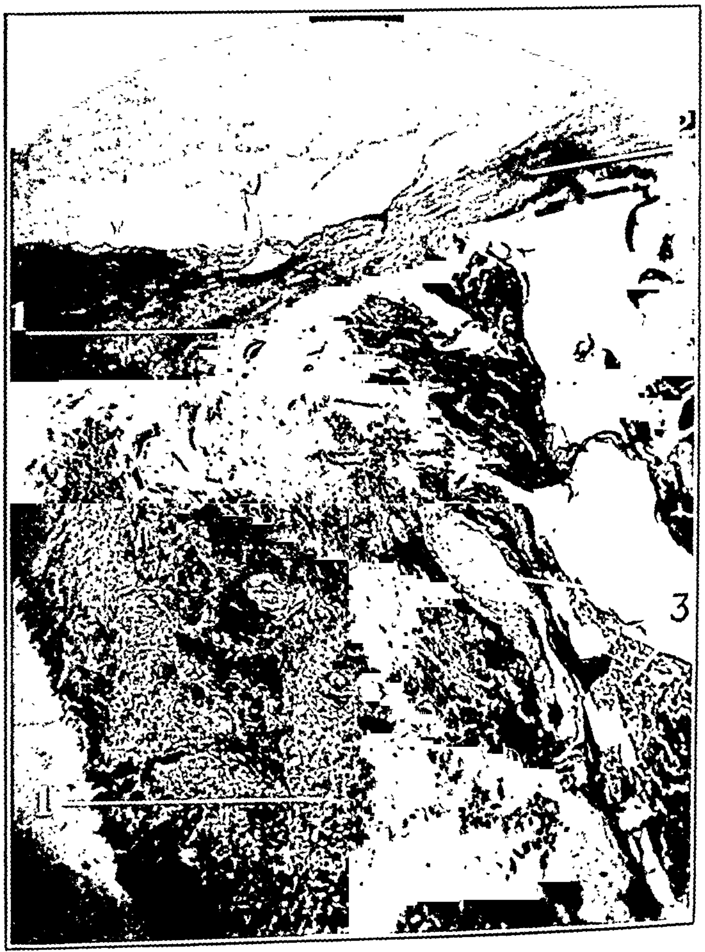

Fig. 13.—Low power photograph of old scar in Figure 12: *1,* normal muscle tissue; *2,* scar shows peritoneal coat with very thin layer of muscle tissue covered with decidua; *3,* placenta on scar.

7. Rupture of the uterus is probably produced by the increased intra-uterine pressure forcing a water wedge into the defective scar.

8. Although well healed scars can withstand the strain of future labors, the frequency of rupture after cesarean section is so much greater than uterine rupture from other causes that the indications for cesarean section should not include such patients as can just as well be treated by the induction of labor at term, pubiotomy, vaginal hysterotomy, or other well known obstetric operations.

Lane Hospital.

ABSTRACT OF DISCUSSION

Dr. J. R. Losee, New York: During the past four months at the New York Lying-In Hospital we have made a histologic examination of a series of cesarean section scars. This work was undertaken to determine, first, if uterine muscle would completely regenerate after being incised, and second, the actual cause of rupture late in a succeeding pregnancy. In this series the tissue was obtained from nine cases in which there was a complete or a partial rupture of the uterus, and from eleven in which the incision was made either through the old scar or adjacent to it at the subsequent operation. Of the nine cases of rupture, two presented a utero-abdominal fistula, in seven the whole scar was laid open, and in three of these the placenta and fetus were in the peritoneal cavity. There was no fat in any of the muscle cells. Of the eleven excised scars, five were moderately strong, and in four of these the placenta was attached directly beneath the wound, which fact suggests that the location of the placenta has little effect on the scar, providing there was firm union after the preceding section. There were six cases which presented rather thin scars, and the location of the placenta was equally divided, three being observed on the posterior wall and three on the anterior wall. From this series I have formulated the following conclusions:

1. The strength of the uterine scar after cesarean section depends on the absence from the wound of infection and foreign material, and on the perfect coaptation of the incised surfaces.
2. A perfectly healed wound leaves the myometrium as strong after operation as before, as far as can be determined by the histologic examination of the tissue in the line of the former incision.
3. A continuous suture in the myometrium adjacent to the decidua may assist in preventing the separation of the cut surfaces by blood clot or lochia in addition to the usual interrupted suture through serosa and myometrium.
4. The placenta in a subsequent pregnancy has little or no effect in weakening the firmly united scar, but if the scar is already weak it may accentuate this weakness.
5. Other than a small amount of fibrous tissue beneath the peritoneum, the myometrium in line with the former incision contains no scar tissue and the uterine muscle regenerates.
6. Rupture invariably takes place through the site of the former scar, and not through the adjacent muscle tissue.
7. Without definite means of estimating the strength of the uterine scar after cesarean section, subsequent pregnancies must be repeatedly observed as they approach term.

Dr. Asa B. Davis, New York: From all parts of the obstetric world reports are accumulating of rupture of the uterus in labors subsequent to former cesarean delivery. One important factor in the lack of strength and proper union in uterine wounds is the absence of muscle sheath, on which we depend so much for strength in other lacerations, as, for instance, in abdominal closure. Another important factor is the uneven thickness, at times, of the uterine muscle, partly due to the retraction and contraction of the uterus. Many times the edges of the uterine wound are of even thickness on both sides. Then accurate apposition and closure by sutures is possible. We see cases, however, in which one side of the uterine wound may be an inch or more in thickness while the opposite side may be one third as thick in places. Here accurate apposition is impossible. Another cause of thin scar may be found in the attempt to secure close approximation; too great tension is made on the sutures. In the healing process these sutures cut into the soft muscle and allow separation, usually more on one side of the uterine cavity. Considerable tension must be made on the sutures, otherwise there is failure of apposition throughout the whole thickness of the edges of the wound.

We find a considerable number of women in active labor subsequent to cesarean section, and often the placenta in these cases is located under the entire length of the former cesarean scar, and yet rupture of the uterus has not taken place. It is doubtful if rupture of the uterus is due to fault in any particular technic in suturing the uterine wound, because no two operators use exactly the same technic, and yet many different operators are reporting cases of rupture of the uterus in labors subsequent to cesarean delivery. Some operators feel sure that their particular method of suturing the uterus is a successful one. I had as much reason to feel that way as any one until after my thirty-ninth cesarean section. Then a rupture through the uterine scar occurred. Since then seven or eight others have been added to my list. All but one have been hours in labor; one mother died.

Dr. James A. Harrar, New York: There is no question that the uterine scar is often an unknown factor in a succeeding pregnancy. We must reduce that factor (1) by avoiding the classical operation when infection is suspected; (2) by proper care in suturing the uterine incision. Rupture occurs in a weakened scar, and it is weak because the original wound sloughed, or because it was not properly sutured.

Dr. Spalding's photomicrographs are valuable because such studies are rare. But I cannot admit that they prove that the syncitial cells erode the scar, comparable to the erosion in a ruptured ectopic pregnancy. The scars were thin, some only peritoneum and mucous membrane. There was an excavation on the under surface because of poor union. But the placenta simply grew into and filled the excavation; it did not make it. Its location under the scar was merely a coincidence.

On the first division at the New York Lying-In Hospital there has been but one rupture in sixty repeated cesarean sections. A thinned scar occurred nine times. In thirty-five the scar was solid, and in fifteen additional it was not materially defective. In six with normal scar the placenta lay directly under the second incision.

Sometimes we have to suture a contracted uterus whose walls are an inch or an inch and a quarter in thickness; here the sutures must be tied firmly. Sometimes, despite ergot and pituitary extract, the uterus remains relaxed and the wall thin. Here the sutures must be tied more loosely to permit of the thickening of the tissue in the grasp of the suture when the uterus contracts down.

Carefully identify and approximate the deeper edges of the incision. The deeper edges tend to retract away from the operator's attention. Do not take too wide a bite with the running suture in the visceral peritoneum, as very wide folds of peritoneum pulled across the line of deeper sutures cause the inner edges of the wound to gape.

In repeated cesarean sections it is better to excise the old uterine scar, whether it is solid or not. A parallel incision would give us two points of doubt in a still later pregnancy, and besides, suture of scar tissue is always poor surgery.

Dr. Nathaniel R. Mason, Boston: In 1910 I carried out a series of experiments with Dr. John T. Williams on pregnant cats and guinea-pigs in the laboratory of surgical research of the Harvard Medical School, with the object of determining the relative strength of scar and uterine wall. The following method was employed: a cesarean section was performed on a pregnant animal. Then, after a period had elapsed equal to the length of pregnancy for the given animal or near the end of a second pregnancy, the animal was killed and a section of the uterine wall containing the scar tested by suspending weights to it. These weights were gradually increased until rupture of the tissue was produced. It was found that rupture invariably took place in the uterine muscle and not in the scar.

In a recent review of 393 cesarean sections performed at the Boston Lying-In Hospital between July 15, 1894, and Nov. 24, 1916, it was found that 106 of these were repeated sections. These 106 repeated sections were performed on 73 women; that is, second sections were performed on 49, third sections on 19, fourth sections on 2, fifth sections on 2 and a sixth section on 1. In many instances these repeated cesarean sections were performed before the advent of labor, but there was also a large number of cases in which the operation was performed after labors of varying length of time. In not a single instance did any one of these 106 patients come to grief, either in pregnancy or labor because of rupture of a former cesarean section scar. In a considerable number of these former cesarean section cases, normal delivery was allowed to occur, and in others labor was terminated by operative vaginal delivery, including forceps operations, breech presentations and internal podalic version followed by manual extractions. No untoward results occurred.

Dr. Charles M. Green lays stress on the importance of allowing active labor to become established before the performance of a cesarean section, in order to obtain a thickened uterine wall. He believes that sutures placed in such a wall produce a stronger, thicker scar than when placed in the thinner wall of a uterus before the advent of labor. Any marked deviation in the method of closure from the principles laid down by Sänger results in a scar of less strength. Dr. Spalding has called attention to the fact that only three cases of rupture were reported between 1895 and 1900 when the classical Sänger operation was the only one performed.

It is well known that great speed in the performance of a cesarean section has been one of the objects striven for almost universally in the past, and is still the aim of some operators, even at present. The result of this practice has left the uterus insufficiently sutured, with faulty apposition of the cut edges of its wall, and a weak thin scar has been the sequence.

Two essential points in the technic of closure of the uterine wall are to be observed. One is the inclusion of the entire thickness of the muscle of the uterus in the suture. The innermost muscular layers often retract to such an extent that great care in the suturing is necessary to secure proper coaptation of the entire length of the incision. The other point is to place a deep suture through the uterine musculature both above the upper angle and below the lower angle of the wound, because at these points splits in the muscular tissue of the uterus frequently occur in the extraction of the body and head of the child. Proper suturing of the wound and healing without infection are indispensable in securing a good scar. A well sutured scar, followed by a convalescence free from infection, can safely be subjected to the strain of subsequent pregnancies and labors. Rupture of such a scar should occur with no greater frequency than does rupture of the normal pregnant uterus.

Dr. Samuel W. Bandler, New York: After ordinary laparotomy, more than 10 per cent. of abdominal wounds do not heal well, so far as a good scar is concerned. We may expect the same in a hurried cesarean section. I never use chromic catgut. I do not consider it an advisable suture for such a delicate structure as uterine muscle. We should, as much as possible, operate in clean cases. The result is always better when the patient has not been examined too much and when operative vaginal procedures have not been tried. If we do not unite the lower areas of the abdominal wall, especially the peritoneum, and vomiting and straining cause the peritoneum to separate, we will, in an occasional case, have a protrusion of the intestines right through up to the skin. The same thing holds in cesarean section cases. We must pay more attention to the depths of the wound, especially the uterine lining. I always give pituitary extract before making the abdominal incision, and therefore have a firmly contracted uterus to sew. I pass No. 2 iodin catgut, often double, through the uterus half an inch from the lower end of the incision so that it comes out through the depth of the wound close to the uterine lining. The needle is then passed through one side and then through the other, catching a good hold of the uterine muscle just above the decidua. This is passed in the same manner as a subcuticular suture is passed. At the upper end the needle then passes through the depth of the wound, coming out through the surface of the uterus half an inch or an inch above the upper margin of the wound. This suture is then pulled on and the uterine lining or decidua is brought closely together. When the ends are tied, the uterine cavity is walled off from the wound and no blood from the cavity of the uterus intrudes itself. The uterine walls themselves bleed scarcely at all, and one can leisurely sew the two raw surfaces together. As the interrupted or continuous suture is passed, the finger in the depth of the uterine wound guards the point of the needle so that it comes out as close to the uterine lining as possible, and dead spaces are thus avoided. A suture is passed to unite the peritoneal edges of the uterus, no attempt whatever being made to invert it. For several days after the operation ergotin is given by needle to keep the uterus contracted to the size it was when the operation was completed.

Dr. J. H. Carstens, Detroit: I am glad that Dr. Bandler objected to chromicized sutures. I use plain catgut; I want it to absorb quickly. All that is needed is to keep the wound together for a few days. I think in all instances of cesarean section for narrow pelvis the patients naturally need another cesarean section. I do not wait until these patients have been in labor for two or three days. I take charge of them and get them in the hospital a week or so before the time of labor and prepare for operation before labor sets in. Then I am sure there will be no strain on the scar, and I will never have any trouble about the rupture of the scar. Once in a while a patient will wait until labor. Then I rush her to the hospital as soon as possible. The first thing I do is to rupture the membrane in order to relieve the pressure. By doing these things there will be fewer cases of rupture than otherwise.

Dr. E. Gustav Zinke, Cincinnati: Recently I have been thoroughly absorbed in the theories concerning the healing of the uterine incision after cesarean section and its behavior in subsequent pregnancy and labor. One of the conclusions I have reached is that it matters little what suture material we use in sewing up the wound, but that it is most important that we have an aseptic wound, that we bring the sides of the incision into perfect apposition and unite the peritoneum securely over it. This procedure is absolutely essential to a firm uterine scar.

Much has been said concerning the dictum, "Once a cesarean section, always a cesarean section." That can hold true only in those cases in which the conditions persist which made the first cesarean section necessary. When hysterotomy is performed for placenta praevia, or eclampsia, a perfect uterine scar will admit of spontaneous delivery in subsequent pregnancies.

But when do we have a perfect scar? Though Whitridge Williams and others maintain that an undisturbed recovery from a cesarean section is the best indication that the uterine wound is firmly united, does this statement hold true in every case? When there is no obstruction in the parturient canal and the presentation and position of the child are favorable, when obliteration of the cervix and dilatation of the os proceed promptly, and the first stage of labor has been completed, the cesareanized woman will deliver herself, undoubtedly, if she has a solid uterine scar. She should, however, be delivered in a hospital so that, if rupture of the wound does occur, the abdomen may be opened at once with a view to saving both lives. But in all cases in which the indications for cesarean section persist, cesarean section is the only proper operative intervention.

Dr. Alfred B. Spalding, San Francisco: I shall not enter into any discussion concerning technic. Dr. Zinke has mentioned a point which to my mind is of the utmost importance regarding cesarean section: The growing list of indications for the operation should be curtailed. I have seen cesarean section performed on women with normal pelves, because their physicians allowed the pregnancy to go overtime, when a dose of castor oil and quinin would have prevented cesarean section. I have seen cesarean section for breech presentation. In eclampsia the mortality is not greatly reduced by cesarean section over other obstetric procedures. In conditions such as placenta praevia, I think we should hesitate before doing cesarean section at the first sign of hemorrhage. We should first ascertain the kind of placenta praevia we are dealing with before resorting to section. Because cesarean section is technically so easy to perform, many men not well trained in obstetrics are dabbling with something they have no business tampering with.

THE COLLOIDAL GOLD TEST

THE PREPARATION OF THE COLLOIDAL GOLD SOLUTION AND ITS APPLICATION TO DISEASES OF THE CENTRAL NERVOUS SYSTEM *

I. The Preparation of the Reagent

J. H. BLACK, M.D., AND LOUIS ROSENBERG, M.D.

To one who has even a casual acquaintance with the literature of colloidal gold solutions, three things are at once apparent: 1. There is a general agreement that satisfactory solutions are difficult of preparation. 2. There are approximately as many variations in technic as there are workers. 3. There is unanimity of opinion that the use of the solution in the diagnosis of diseases of the central nervous system has a very definite value.

The major portion of the work done in this country has been carried on with a more or less close adherence to the technic of Lange,[1] variations being introduced by the individual worker in the effort to produce uniform results. It is quite true that many men have been able to produce satisfactory solutions — some of them with considerable regularity — but the inability to secure continued duplication of results, together with the irregular behavior of some of these apparently good solutions, makes it evident that all the conditions necessary to the production of a good solution are not known, and that the standards by which these solutions are judged are insufficient.

A very marked advance in our knowledge of these conditions was made by the report of Miller, Brush, Hammers and Felton.[2] They propose a method which, if carefully followed, will give uniform results, and devised means by which these solutions which appear satisfactory but are not can be detected. Our own experience led us quite early to the conclusion that their claims were well founded and their technic quite dependable. Feeling, however, that the requirements as to equipment, time and complexity of detail might serve to deter many men from as general a use of the reagent as its value deserves, we entered on this work with the purpose of determining to what extent simplification might be carried without interference with uniformity of results. The technic of others has been used on occasion to check findings and with the desire to clear up certain points, but the work of Miller and his associates was the basis of this work and was accepted as standard technic.

As soon as it was evident that this method produced uniformly good solutions, work was begun retaining the original technic with the exception of one factor, and variations in this one factor — all other conditions remaining constant — were used to determine their influence on the character of the solution. Our findings, as based on the preparation of 367 solutions, can probably best be presented by separate, brief statements relative to each factor, with tables appended detailing experimental data when it is believed such information might be of value.

Distilling Apparatus.—The apparatus used for the first thirty-nine solutions consisted of resistance glass flasks, block tin tubing, and cork connections. The tin tube was bent near one end forming a wide arc. The short vertical section of tubing projected through a tight fitting cork into the distilling flask. The long vertical section of tubing was surrounded by a condenser jacket and passed through a loose fitting cork into the receiving flask. This simple apparatus gave entire satisfaction. For the greater portion of the work a 3 gallon copper, tin-lined still was used.

Method of Distillation.—The flame is turned high and the first distillate comes over rapidly, while no water flows through the condenser jacket, the steam cleaning the tube. After about 200 c.c. with the small apparatus, and 1,000 c.c. with the larger, have come over, the flame is cut down until the water flows in discrete drops into the receiving flask. Distillation is stopped when approximately four fifths of the contents of the distilling apparatus have come over.

Number of Distillations.—Beginning with one distillation with a Stokes still followed by two in the above described apparatus, we soon found that, by carefully distilling, a single distillation with this apparatus without preliminary treatment was entirely satisfactory, and this became routine procedure. Water once distilled in a Stokes still was found to vary so widely at different times that it was not to be depended on, although, in one instance, excellent solutions were obtained by its use.

Storage of Water.—Singly distilled water has been stored at room temperature in clean resistance glass flasks and has proved satisfactory after thirty-four days. No attempt was made to determine this further. In ordinary glass the water has been found satisfactory after forty-two days. We believe that the age of carefully distilled water has no influence on the character of the gold solution. Indeed, Zsigmondy[3] states that doubly distilled water improves with age through a settling of the particles contained.

Cleaning of Glassware.—New glass was used and was, of course, used for nothing else. Hot soap and water for thirty minutes was followed by careful brushing under the tap; then hot dichromic acid solution for thirty minutes followed by careful rinsing under the tap, then with distilled water. If this procedure was carried out as the initial cleansing, it was found that much of this could be omitted at subsequent times. Beakers used on one day stood over night filled with tap water and were used with satisfaction after careful brushing and rinsing. Beakers stood inverted on filter paper on the laboratory table for one week and were used after only brushing and rinsing. Good solutions resulted. Pipets used for measuring reagents were wrapped in filter paper after use and used twelve days later after rinsing with distilled water. Good results were obtained. Glassware which is not thoroughly clean is, in our opinion, the cause of the vast majority of protected solutions. Glass cleaned and used according to the foregoing statements should eliminate protected solutions with a minimum of labor.

Reagents.—Merck's chemicals were satisfactory, as were Baker's. Schering and Glatz' formaldehyd solution gave satisfaction. It was found that all reagents could be used as stock solutions. These were frequently used over a period of thirty days. Indeed, one formaldehyd solution was found satisfactory after three months. The only precautions used were to insure clean water, clean flasks kept tightly corked, and accurate measurements.

Preparation of Colloidal Solution (100 c.c. being used as a basis for discussion).—A beaker containing 100 c.c. of water is placed on wire gauze over a high flame. One c.c. of the 1 per cent. gold chlorid solution is added, followed by 0.7 c.c. of the 2 per cent. potassium carbonate. Heating is rapid, and at incipient boiling 0.5 c.c. of 1 per cent. formaldehyd is added. The solution should be vigorously stirred until reduction is complete. This should not require more than two minutes.

Comments on Technic of Preparation.—We have not found it necessary to add the gold and alkali at any particular temperature. Satisfactory solutions have been made by adding reagents to cold water and rapidly heating to boiling. The temperature at which the formaldehyd is added is, however, of much importance. If added at a low temperature, vaporization of a considerable quantity of formaldehyd may occur, leaving an amount insufficient for complete reduction of the gold. If added at a high temperature, the rapidity of the reaction is so increased that the loss by vaporization is negligible. Using the stated quantity of formaldehyd, we have obtained good solutions with equal ease at 90 C. and with vigorous boiling.

The, use of oxalic acid has, in our experience proved unnecessary.

DISCUSSION

The equation representing the reactions occurring in the preparation of the colloidal gold solution is, we believe:

$$9K_2CO_3+4AuCl_3+6HCHO=6HCOOK+2Au_2+3H_2O+9CO_2+12KCl$$

This equation may be proved by some results of our work, and it throws much light on other phases of the problem.

Influence of Alkali.—Calculation from the equation shows the amount of alkali required to maintain equilibrium with the gold chlorid used to be 0.01027 gm., which is contained in 0.513 c.c. of the 2 per cent. solution. It is evident that the formaldehyd is oxidized to formic acid, the amount of acid produced being neutralized by the amount of alkali over and above that required for the initial equilibrium with the gold. This added amount, according to the equation, is 0.171 c.c. of the 2 per cent. solution, making a total of 0.684 c.c. of the 2 per cent. solution required.

Table 1 illustrates a series of colloidal gold solutions made with potassium carbonate, varying in amount from 0.4 to 1.5 c.c. It will be noted that increase of alkali above 0.684 c.c.—the amount calculated from the equation—causes no shimmer, but gives beautiful solutions until more than 1 c.c. was used. Then the solutions were quite turbid and reduction occurred immediately on the addition of the formaldehyd. These solutions were, of course, alkaline. Decrease of alkali could be carried to 0.5 c.c., at which point pale blue solutions were obtained only after prolonged heating. Theoretically, we should expect to find reduction taking place in direct ratio to the decrease in the amount of alkali, the solution becoming lighter in color as the amount of reduced gold decreases, and the limit at which reduction is completely absent should be somewhat below the amount calculated as required. That this is borne out by the experimental data may be seen.

TABLE 1.—INFLUENCE OF ALKALI

Amount of 2 Per Cent. Solution C.c.	Reaction	Character of Solution
.4	....	No reduction
.5	Alkaline	Pale blue
.515	Alkaline	Reddish-blue
.525	Alkaline	Decided shimmer
.550	Alkaline	Faint shimmer
.575	Alkaline	No shimmer
.6	Alkaline	No shimmer
.625	Neutral	No shimmer
.650	Neutral	No shimmer
.675	Neutral	No shimmer
.7	Neutral	No shimmer
.725	Neutral	No shimmer
.750	Alkaline	No shimmer
.775	Alkaline	No shimmer
.8	Alkaline	No shimmer
.825	Alkaline	No shimmer
.850	Alkaline	No shimmer
.875	Alkaline	No shimmer
.9	Alkaline	No shimmer
.925	Alkaline	No shimmer
.950	Alkaline	No shimmer
.975	Alkaline	No shimmer
1.0	Alkaline	No shimmer
1.25	Alkaline	Turbid
1.5	Alkaline	Turbid

Although 0.513 c.c. is the amount of alkali required for equilibrium with the gold, reduction will occur at as low as 0.5 c.c., but even at 0.525 c.c. reduction is evidently incomplete. Addition of further alkali to these bluish solutions produces an immediate change to the red of a fully reduced gold, but we were unable to get brilliant, transparent solutions in this way. We believe we are dealing here with a partial reduction of all the gold, and that the situation is analogous to the partial reduction with minimum amounts of formaldehyd which is discussed below. The partial reduction here may be explained on the basis that, according to the mass law equilibrium, there must be a few potassium carbonate molecules which by their dissociation would yield the small amount of alkali necessary to permit partial reduction. One might expect a cycle which would eventually lead to complete reduction. This, however, is prevented by the presence of the potassium chlorid (and potassium formate), which represses dissociation of the few free potassium carbonate molecules. When it is remembered that formaldehyd acts as a reducing agent only in an alkaline medium, we have a possible explanation for the behavior of the solutions which Miller and his associates found did not reduce with the stipulated amounts of reagents. Using oxalic acid, measured in drops, which probably permitted variation in amount, this probably neutralized the free alkali and prevented reduction.

Influence of Formaldehyd.—Calculated from the equation, the amount of formaldehyd required to completely reduce the gold is 0.001486 gm., the amount contained in 0.1486 c.c. of the 1 per cent. solution. Reference to Table 2 shows that the amount of formaldehyd may be increased to 5 c.c. without producing any shimmer. Decrease in amount was possible to 0.13 c.c. Below this point blue, opaque, solutions resulted. Below 0.45 c.c. the solutions were alkaline. The time required for reduction varied inversely with the amount of formaldehyd. If, to those solutions whose color is unsatisfactory because of the use of insufficient formaldehyd, further formaldehyd is added after reheating the solution, beautiful *satt rot* (intensely red) solutions which are neutral in reaction may be obtained. We have been able to convert an opaque, blue, alkaline solution, made with only 0.1 c.c. formaldehyd, into a beautiful, neutral solution by this method. By reference to Table 3 it will be seen that these "corrected" solutions give typical curves with a paretic spinal fluid.

Influence of Carbon Dioxid.—With an ammonia-free water it should be evident that "the gases in the water"[4] play no part in the determination of the quality of a solution, for carbon dioxid is produced in the reaction; and whether the temperature is maintained at 90 C. or brought to boiling is immaterial, for the difference in the carbon dioxid coefficient at 90 C. and at 100 C. is too slight to affect the solution, and even at 100 C., carbon dioxid, is not entirely removed, but has the absorption coefficient of 0.2438.[5]

Inflence of Method of Heating.—Solutions made properly are neutral in reaction to alizarin. If heating has been slow and the formaldehyd is added before the boiling point is reached, vaporization of the formaldehyd will be excessive, resulting in incomplete reduction and alkalinity. Depending on the amount of formaldehyd lost by evaporation, the solution may be a deep red, a light red, or blue and opaque. These variations may be produced without varying the amount of formaldehyd, if the method of heating is changed.

Solutions made in the ordinary way, without stirring after the addition of the formaldehyd, usually do not give brilliant color without shimmer; yet stirring may be dispensed with if the solution is made in the water-bath.

TABLE 2.—INFLUENCE OF FORMALDEHYD

1 Per cent. Solution, Quantity C.c.	Time for Reduction	Reaction	Color
.1	Slow	Alkaline	Blue
.11	Slow	Alkaline	Blue
.12	Slow	Alkaline	Blue
.13	Slow	Alkaline	Good
.14	Slow	Alkaline	Good
.15	2 minutes	Alkaline	Good
.2	2 minutes	Alkaline	Good
.25	1⅚ minutes	Alkaline	Good
.3	1⅔ minutes	Faintly alkaline	Good
.35	1 7/12 minutes	Faintly alkaline	Good
.4	1½ minutes	Faintly alkaline	Good
.45	1 9/20 minutes	Neutral	Good
.5	1⅙ minutes	Neutral	Good
1.0	1 minute	Neutral	Good
2.0	½ minute	Neutral	Good
3.0	⅓ minute	Faintly acid	Good
4.0	⅕ minute	Acid	Good
5.0	⅕ minute	Acid	Good

Since it is evident that the limits within which the alkali and formaldehyd give good solutions are wide enough to embrace any amount of inaccuracy of measurement of a careful worker, and the carbon dioxid tension can have no influence on the solution, and since the manner of heating produces such definite effect, we feel that we are justified in believing that if the technic described above is followed, solutions with shimmer—slight or excessive—can be due to only one cause, namely, slow or irregular heating.

Catalytic Oxidation of Formaldehyd by Colloidal Gold.—Lange's original technic[1] called for 1 c.c. of a 2 per cent. potassium carbonate and 1 c.c. of a 1 per cent. formaldehyd. Neutral solutions can be obtained by this method. Since this is more alkali than is required according to the equation given above, the neutrality of reaction can be explained only on the basis of the colloidal gold acting as a catalyst and causing oxidation of the formaldehyd in excess to formic acid, which then reacts with the excess potassium carbonate. Indeed, it seems probable that solutions made with smaller amounts of alkali are neutral for the same reason. If the calculated amount of potassium carbonate is used, the final reaction of the solution we would expect to be alkaline, owing to the hydrolysis of the potassium formate and the potassium carbonate liberated from its equilibrium with the gold chlorid when the latter is completely reduced. Since the solutions are not alkaline, we believe that the result is obtained through the catalytic action of the colloidal gold on the excess formaldehyd. The formic acid so formed combines with the potassium carbonate liberated and, if sufficient in amount, will also repress the dissociation of potassium formate. Proof of this supposition seems to be furnished by three facts: 1. Many solutions made by the prescribed technic may be slightly alkaline immediately at the completion of reduction, but become neutral after the lapse of a few minutes without further treatment. 2. Solutions made with a known excess of alkali may be made neutral by reheating and adding additional formaldehyd. 3. Solutions which have been standing for some time and have become alkaline may be made neutral by heating and adding formaldehyd. These "corrected" solutions give typical curves with spinal fluids (Table 3).

Correction of Solution.—It is interesting to note that, while blue solutions made with insufficient formaldehyd may be corrected, and those alkaline from preparation with excess alkali or from standing may be neutralized, and that these may be satisfactorily used in testing spinal fluids, we have not been able to correct the turbidity due to marked excess of alkali or to irregular heating.

The fact that alkaline solutions may be made neutral simply by heating and adding formaldehyd may be used to advantage in the correction of the reaction (if this is desired), in that it requires no particular accuracy of manipulation or of quantity, as the formaldehyd may be added 1 c.c. at a time until the reaction becomes definitely neutral. It may be added that if evaporation of water is considerable, either during the preparation of the solution or in correcting its reaction, water may be added to restore the original volume.

Standards for Solutions.—The standards to which a solution must conform to be adjudged satisfactory have been stated by Miller and his associates to be as follows:

1. The solution must be absolutely transparent and preferably brilliant orange red or salmon red.
2. Five c.c. of the solution must be precipitated in one hour by 1.7 c.c. of a 1 per cent. sodium chlorid solution.
3. It must be neutral when used.
4. It must give a typical reaction with a known paretic fluid.
5. It must show no more than a change to red-blue with a known normal fluid.

---

[4] Glaser: Neurol. Centralbl., 1914, **33**, 688, 748. Lee and Hinton: Am. Jour. Med. Sc., 1914, **148**, 33.

[5] Landolt-Bornstein: Tabellen.

Our work leads us to conclude that: 1. Solutions which are transparent, but show a slight shimmer by reflected light, may be used satisfactorily. The curve will not differ from that given by a brilliant solution. 2. If a solution is protected, so as to make it even slightly refractory to precipitation by the amount of sodium chlorid mentioned, it should not be used. 3. Solutions made with 1 c.c. potassium carbonate—0.3 c.c. above the required amount and, consequently, markedly alkaline to alizarin — give curves practically identical with those given by normal solutions (Table 3). With the technic described above we have never obtained acid solutions. It is quite possible that the acid solutions obtained by Miller and his associates were those in which they found reduction not occurring with the specified amount of formaldehyd. This was probably due to the removal, by the oxalic acid used, of the alkali required for the reducing action of the formaldehyd. If then further formaldehyd was added, the addition of 1 or 2 drops of alkali, sufficient to bring the solution to an alkaline reaction, permitted reduction. Meanwhile the very considerable excess of formaldehyd which was used was catalytically oxidized to formic acid and the reaction made acid to alizarin. 4. Solutions satisfactory in color and not protected should show typical curves with abnormal fluids and no change with normal fluids.

TABLE 3.—CURVES OBTAINED

With Known Paretic Fluid:	
1. Brilliant, neutral solution	5555521000
2. Neutral solution with decided shimmer	5555552100
3. Blue-red solution made with 0.1 c.c. HCHO	4445555555
4. No. 3, corrected by adding HCHO	5555555200
5. Solution made with 3 c.c. HCHO	5555552100
6. Alkaline solution made with 0.525 c.c. K_2CO_3	5555552100
7. Solution made with 0.5 c.c. K_2CO_3 and corrected	5555555200
8. Alkaline solution made with 1 c.c. K_2CO_3 and 0.5 c.c. HCHO	5555521000
9. No. 8, after standing three weeks—very alkaline to alizarin	1223210000
10. Lange's technic—reaction neutral—used fresh	5555531000
11. Lange's technic-alkaline from standing three weeks.	2434410000
With Known Syphilitic Fluid:	
12. No. 1	1232110000
13. No. 8	1233210000
14. No. 10	2234110000
15. No. 4	1232200000
16. Brilliant solution alkaline from standing two months—corrected by reheating and adding HCHO	1232110000

CONCLUSIONS

1. Singly distilled water may be stored satisfactorily in clean glass for many days.

2. Protected solutions are usually due to unclean glass.

3. Reagents may be used satisfactorily as stock solutions.

4. If technic is carefully followed, turbid solutions are due to slow or irregular heating and cannot be corrected.

5. Formaldehyd should be added at from 90 C. to boiling.

6. Solutions poor because of use of minimal amounts of alkali or formaldehyd may be corrected, the latter, so that they may be used clinically.

7. The use of oxalic acid is not necessary and is possibly occasionally responsible for failure of reduction.

8. The presence of carbon dioxid is of no consequence.

9. Solutions alkaline at the time of preparation or on standing may be made neutral by reheating and adding formaldehyd.

10. Solutions showing a slight shimmer may be used satisfactorily.

11. Solutions definitely alkaline at the time of preparation, if of good color, may be satisfactorily used. Those alkaline from standing give irregular curves.

II. The Clinical Application of the Colloidal Gold Test

R. B. McBRIDE, M.D.

In view of the fact that the preparation of a satisfactory solution for the colloidal gold test has become a simple problem, and that the performance of the test is attended with few chances of error, it would add greatly to our diagnostic and prognostic ability if we were able to establish definite and certain behavior of the test under identical clinical conditions and circumstances. With the view of adding our data to those already accumulated, this report is made.

The cases coming under our observation will be classed as syphilitic and nonsyphilitic. Of the latter there are many, but the collection is heterogeneous and does not yet seem suitable for the basis of definite conclusions. Our experience with syphilitic diseases of the central nervous system embraces, to date, fifty-nine patients on whom 169 examinations of the spinal fluid were made. All of these gave definite clinical evidence of some central nervous system involvement. With this comparatively small number our results have shown a uniformity in some particulars that leads us to feel that they are worthy of presentation as a basis for further study.

Of the fifty-nine syphilitic cases, fifty-six gave a positive colloidal gold test. The three cases that were negative to this test were classed by our clinical findings as cerebrospinal syphilis, and gave, respectively, sixteen, twenty-one and sixty-two cells. All of these gave positive Wassermann tests of the blood, while the one showing sixteen cells gave also a positive Wassermann on the spinal fluid.

Thirty-six of the fifty-nine cases gave positive Wassermann tests on the spinal fluid. There was no parallel to be drawn here except that the paretic curve was more often associated with a positive Wassermann than was any other curve. Nineteen of the fifty-one patients whose blood was examined gave positive Wassermann tests of the blood. All of the fifty-nine cases showed a pleocytosis ranging from nine to 120 cells. There were no parallels to be drawn here, as one case of syphilitic meningitis gave 120 cells with a positive Wassermann test of the spinal fluid and a marked curve in the meningitic zone, while a case of incipient tabes gave 120 cells and the spinal fluid was otherwise negative. Later this case of tabes developed a curve in the meningitic zone with a cell count of thirty-six. Solomon and Southard[6] have already pointed out that the colloidal gold reaction indicates one sort of physicochemical situation in the cerebrospinal fluid; the lymphocytosis indicates another type of reaction on the part of the nervous system. The number of cells accompanying a paretic curve varied from twelve to sixty, while with the meningitic curve they varied from twelve to 120. Of all our cases twenty to thirty cells was the average.

A positive globulin test was found in all cases, while reduction of Fehling's solution was seldom noted.

As to the reliability of the colloidal gold test, we found that of five cases diagnosed clinically as paresis, all gave curves in the paretic zone. However, among eleven tabetics, the paretic curve was present in three cases; six gave meningitic curves, and two were in the syphilitic zone. Thirty-nine cases of cerebrospinal syphilis gave three negative curves with the colloidal gold test, as noted above; twenty were in the meningitic zone, and fifteen were in the syphilitic, and one, in whom paresis could not be entirely excluded, gave a paretic curve.

---

[6] Solomon and Southard: Jour. Nerv. and Ment. Dis., 1917, 45, 230.

We believe there is no such thing as a provocative colloidal gold reaction. While several fluids showing a negative Wassermann test became positive after treatment, no change was noted in the gold test.

Red blood cells—or blood plasma—appeared, at times, to cause disturbance in the final reading, but no definite conclusion can be drawn from our series. A case of cerebrospinal syphilis with a positive Wassermann test on the spinal fluid and a syphilitic curve gave later, when many red cells were present, a paretic curve. Two cases of cerebrospinal syphilis with negative Wassermann tests on the spinal fluid and syphilitic curves gave later, with red cells present, the same curve, the blood causing no evident change. A case of tabes with positive Wassermann test on the spinal fluid and paretic curve, with red cells present, gave complete precipitation in all tubes.

Vigorous intravenous and intraspinal treatment tends to bring all positive tests on the spinal fluid toward the negative. Our experience has been that the colloidal gold test is the last to become negative, and hence is the most reliable as a prognosite guide. It is also our experience that the colloidal gold test is the earliest reliable test to be found in the spinal fluid of syphilitic patients, being frequently earlier than the Wassermann reaction. Pleocytosis and increased globulin content are excluded since they are present in all inflammatory conditions of the meninges. We have been unable in any wise to prove, but feel justified in assuming, that a given spinal fluid passes successively, during the progress of sphyilitic involvement, from syphilitic to meningitic to paretic curves, and vice versa, during intensive treatment. That is to say, the condition producing the change in the state of the colloidal gold is the same in all zones and merely present to a greater or less degree. Further observation will probably prove or disprove this assumption. We have several cases that have, under treatment, receded from the meningitic to the syphilitic zone, and some of these have finally become entirely negative. A case of clinical tabes which gave a paretic curve, with a positive Wassermann test on the spinal fluid and twenty cells, gave, after treatment, a meningitic zone curve, a negative Wassermann, and thirty cells. Clinically there was much improvement.

We believe that in active syphilis of the central nervous system, a positive colloidal gold test is always accompanied by one or more other indications of involvement of the central nervous system. Pleocytosis and increased globulin are always associated, but there is no constancy of association of other tests. There are, unquestionably, cases in which the colloidal gold curve will persist after all other findings are negative. This occurs probably in those cases in which no intraspinal treatment has been given, but which have reached apparent cure with only systemic medication. In these cases we believe the curve has little or no prognostic value. The patient is probably cured. In those instances in which repeated tapping of the canal has been done, we have found that the curve, while persisting longer than other findings, becomes negative if the patient receives a clinical cure.

CONCLUSIONS

1. A colloidal gold reaction typical for syphilis is nearly constant in cases of syphilis of the central nervous system.
2. This reaction is more delicate than the Wassermann tests on the blood and spinal fluid and more reliable than pleocytosis and globulin content. Curves are, of course, given with other conditions than syphilis, but we believe the curves mentioned above to be specific.
3. The test is the most reliable of the various tests as a diagnostic aid, and is the best guide for prognosis during treatment, probably tending to become negative in a regular and constant order.
4. Known paretics always give a paretic curve; however, there is obtained occasionally a paretic curve in other phases of central nervous system syphilis.
5. There is no provocative colloidal gold test.
6. The presence of red blood cells—or plasma—in the spinal fluid often vitiates the result of the test.

VEGETABLE FOODS FOR THE DIABETIC *

RUTH A. WARDALL
IOWA CITY, IOWA

Even a slight experience in the planning of the diet for the diabetic readily convinces one that careful thought and work along this line are needed, and that time and effort spent in an attempt to enlarge the meager diet list of such patients will be fully justified. With the necessary elimination of practically all fruits and many vegetables, because of their carbohydrate content, the diet of the diabetic becomes very much restricted and monotonous and undesirably reduced in bulk. The withdrawal of fruits and vegetables from the diet is keenly felt, and the diabetic craves the variety that is furnished by this type of food.

The usual analysis of our ordinary food materials gives their percentage composition in terms of so-called protein, fat, carbohydrate, ash and water, and from such data lists of foods have been compiled for the use of the diabetic. A familiar arrangement is that in which fruits and vegetables are classified into 5, 10, 15 and 20 per cent. carbohydrate groups, and from such lists definite portions are daily assigned to the diabetic in accord with his tolerance. Table 1, from Joslin's "Treatment of Diabetes Mellitus," gives an illustration of such a classification.

The figures of percentage composition of foods are capable of definite interpretation from the chemical, but not from the physiologic point of view. The end-products of a chemical analysis are not necessarily a safe index to the end-products of the same materials when taken as food into the animal organism. This is a well known fact, but one needs to bear it in mind when considering the amount of carbohydrate, and especially in the case of diabetes, in which the carbohydrate of the diet is so important a factor in the treatment. According to chemical constitution, cellulose and the hemicelluloses are as truly carbohydrates

---

* From the Sheffield Scientific School, Yale University.

as the sugars and starch, and the hemicelluloses are easily hydrolyzed with acid to the same simple sugars that result from the digestion of complex sugars and starch. Agar-agar is characterized by the hemicellulose galactan, but utilization experiments have shown that agar-agar is not to any appreciable extent a source of available carbohydrate for man. Inulin has been suggested as a possible carbohydrate for the diabetic because it yields levulose on splitting and there is some indication that levulose can be better tolerated than glucose. The higher animals have no enzyme capable of splitting inulin, and therefore its conversion into levulose in the body is dependent on the acid of the gastric juice. Lewis[1] has shown that inulin is poorly utilized by man. Intestinal fermentation attends its use, and the value of inulin in the diet is questionable. Swartz[2] has given numerous other illustrations of the failure of man to utilize certain complex carbohydrates.

* Reckon available carbohydrates in vegetables of 5 per cent. group as 3 per cent, of 10 per cent. group as 6 per cent.

Since the carbohydrate-free foods are limited in number, efforts have been made to remove or reduce the carbohydrate naturally occurring in some of our foods, thereby making them suitable for the diabetic diet. The "thrice-cooked vegetables" represent such an attempt. In preparing them the water is changed twice during the cooking process and thrown away, carrying along a certain amount of soluble material. To learn something of the condition of the food after this treatment, "thrice-cooked vegetables" were prepared and analyses made to determine the extent to which carbohydrate is removable by water extraction. As might have been suspected, it soon became evident that there is a variation in the effectiveness of the method depending on the vegetable used.

A preliminary series of experiments was planned to gain a rough idea of the relative amount and nature of the material that might be removed by water extraction. In order to facilitate the process, the solid vegetables were cut into small pieces or slices. The vegetable was well covered with cold water, heated to the boiling point, and cooked for several minutes. This first water extract was drained off, fresh cold water added, and another extract made in the same way. This process was repeated until an extract was obtained that contained no reducing substance. Each extract when drained off from the vegetable was concentrated and made up to a given volume, and then its reducing power was tested qualitatively with Benedict's solution. All of the reducing extracts were united, and a determination of the reducing substance in this total extract was made by Benedict's method for quantitative estimation of glucose. The reducing substance of the total extract was calculated as glucose. In many instances the color of the extract interfered with the quantitative test, and such extracts were therefore clarified and decolorized by the use of lead acetate, the excess of the latter being removed with hydrogen sulphid gas. The nature of the reducing substance was further tested with yeast to determine its fermentability. The residue of the vegetable, after all extractions were made, was finely ground and submitted to amylolytic digestion with saliva, and the salivary extract was tested for reducing substance. When the color did not interfere, tests for starch were made with iodin. All figures are calculated on the edible portion of the food.

Table 2 reveals the fact that at the end of the third extraction — which fairly represents the "thrice-cooked" vegetable—some of these materials were comparatively freed from reducing substance while others were not. The table also shows enough difference in the amount of reducing substance to suggest the wisdom of a choice among these illustrative vegetables in making up a diabetic diet. A dietitian recently remarked that diabetic patients do not tolerate cauliflower very well. This is not surprising in view of the fact that the cauliflower is not only comparatively rich in reducing substance, but is also slow to give this up by cooking, as evidenced by the number of extracts showing reduction. In all of these vegetables in which the extract reduces, it also ferments with yeast. No further attempt was made to identify the reducing substance. Most of these vegetables were evidently very poor in starch, for salivary digestion of the residues in very few cases resulted in an extract that showed any reducing substance. The common use of spinach in the diet of the diabetic is easily justified by the low carbohydrate content, by the ease of its extraction, and by its good color and appearance even after several extractions. Fortunately, spinach retains its flavor to an appreciable extent. Celery also deserves a place in the diet of the diabetic. The ordinary field mushrooms (*Agaricus campestris*) are unique among the foods examined. These seem suitable for use, without modification, in the most restricted diet, and may be prepared alone or in combination with other less tasty products for the sake of flavor. The value of the mushroom is in its flavor, for it is seen to have no extractable carbohydrate, and Mendel[3] has shown that its nitrogen does not occur as protein, but in an unavailable form. This variety of mushroom may be found in the fields in the proper season, and it is not very difficult to cultivate. Mushrooms both fresh and dried are fairly common in many of our markets and are frequently obtained at a very reasonable price.

The findings in the foregoing experiments are only preliminary to further work. The analyses should be repeated so that the results will represent averages from many more tests, and a number of other foods should be examined. The results already obtained are suggestive, however, of helpful possibilities in the preparation of food for the diabetic.

* Atwater and Bryant: Chemical Composition of American Food Materials, Bull. 28, Office of Experiment Stations, U. S. Department of Agriculture.

Following the principle used in the extraction of the sugar beet in the commercial preparation of sugar, similar treatment of a few other vegetables has been tried in an effort either to render them free from available carbohydrate or materially to reduce the amount. In this series of experiments the vegetables were finely sliced, well covered with water at 60 C. (140 F.) and allowed to soak. At intervals of ten or fifteen minutes, the water having cooled to 45 or 40 C. (113 or 104 F.) was drained off, and fresh water at 60 C. added for the next extraction. This process was repeated until, on removal of a portion of the vegetable and thoroughly cooking it at the boiling temperature, an extract was obtained which gave no reduction test.

Table 3 gives the results of the boiling water extraction and of the extraction at 60 C. The possibilities in the latter method have not been fully tested as yet. The extraction at the lower temperature seems equally efficacious in the case of some vegetables, but it is not adapted to the preparation of cabbage, for example, and probably not to some others. The extraction at 60 C. has the advantage of impairing color and texture less than the repeated extractions with boiling water.

To the normal person, with his liberty of choice of food materials, these extracted vegetables are not unusually tempting; but to the diabetic, with his restricted range of selection, they do offer something of interest. One diabetic was so much pleased with carrots prepared by the 60 C. extraction that he has planted this vegetable in his garden to assure his supply. It is evident that vegetables could be so treated and preserved for subsequent use either by canning or drying. By the use of a current of air from an electric fan, the carrots extracted at 60 C. can be easily and thoroughly dried in three and a half hours. They retain their color perfectly when desiccated in this rapid manner, and after soaking and cooking show little variation from the fresh carrot when cooked.

As it was realized that sucrose and other disaccharids, as well as the hemicelluloses, would not be detected in the foregoing direct examination of these vegetables for reducing substances, a more detailed analysis of carrots was made comparing the results of the extractions at boiling temperature and at 60 C. in experiments in which the extracts and residues were tested for reduction both before and after hydrolysis.

It is apparent that the carbohydrate of the carrot occurs almost entirely in the form of a soluble reducing substance, for neither salivary digestion nor hydrolysis adds materially to the total reducing power. This is not the result that occurs with the beet, for instance, for the carbohydrate of the beet occurs largely in the form of sucrose, and only a trace of reducing substance is found until after hydrolysis.

TABLE 3.—EFFECT OF TEMPERATURE ON EXTRACTION

Cooked vegetable	0	....	Trace	0	+	0
Extract	....	....	0	0	+	0
Sixty C. Extraction						
Time required to free from reducing substance	1 hour	? Little affected	1½ hrs.	2 hrs.	1 hour	3½ hrs.

An attempt was made to extract carrots with cold water. The finely sliced vegetable was put into a heavy bag, which was fastened to the tap, and water at full pressure was forced through the bag for twenty hours; but this plan of diffusion with cold water removed only a very small amount of the reducing substance of the carrot.

These tests are preliminary to more extended work along the same and similar lines. Other foods may well be modified by these methods, and other methods of modification may suggest themselves for trial.

CONCLUSIONS

Repeated water extraction as employed in the "thrice-washed" or "thrice-cooked" vegetables is more effective in removing carbohydrates from some foods than from others.

The effectiveness of the extraction at 60 C. in the case of the beet and carrot suggests the possible advantage of using the lower temperature in the preparation of other foods.

TABLE 4.—COMPARISON OF RESULTS OF EXTRACTIONS AT BOILING TEMPERATURE AND AT 60 C.

	Reducing Substance per Hundred Gm. Carrots	
	100 C. Extraction	60 C. Extraction
Total extract:		
Reducing substance before hydrolysis.......	1.5 gm.	1.2 gm.
Reducing substance after hydrolysis........	1.9 gm.	1.6 gm.
Residue:		
Reducing substance after hydrolysis........	0.5 gm.	0.7 gm.
Reducing substance after salivary digestion	Trace	0.14 gm.

If the soluble carbohydrate is in an available form, the repeated extractions are justified, provided that the resulting product is still reasonably palatable. If, however, the carbohydrate is not available, as in the case of mushrooms, the process is useless.

Information concerning the nature and physiologic significance of the carbohydrate will lead to a rational method of procedure in the preparation of the foods.

PROLAPSUS UTERI AND ITS TREATMENT *

A. J. RONGY, M.D.
Fellow of the American College of Surgeons
NEW YORK

It is not the purpose of this short paper to bring forth a new method for the treatment of uterine prolapse, nor is it my intention to enter into a detailed discussion of the technic of the various operations now in vogue. I feel that much has been said and written on the subject. To me it seems that the entire subject of pelvic hernia has in the past been viewed from the standpoint of repair only. The inventive powers of the gynecologist have been heretofore directed toward the development of a newer and better technic for the construction and their replacement of tissues and organs in the proper places. True, this resulted in the development of one of the most ideal operations, and one which may be performed in the case of the largest percentage of patients suffering from uterine prolapse, namely, "the vaginal fixation or interposition operation."

This operation, if well performed in properly selected cases, completely cures the patient. No other single or combined surgical procedure accomplishes such desirable results. It is surprising to note that many gynecologists, however, still resort to other means to correct this condition, the most troublesome to which middle-aged women are subject. Is it because the interposition operation presents a more difficult technic? Or is it because a great number of gynecologists are better trained in the older methods and refuse to progress?

It seems to me that in the light of our present knowledge there should not be a difference of opinion as to the indications and contraindications for this operation. However, while it is true that we have perfected a good surgical technic for the cure of pelvic hernia, yet it appears to me that no attempt has been made by either the gynecologist or the obstetrician to seek deeply into the causes which bring about the various degrees of hernia of the vaginal vault, resulting from childbirth. Poor obstetrics is usually the reason assigned in a large percentage of cases. Now, is this true? It has been my good fortune to be associated with large obstetric services since the days of my early training. I had unusual opportunities to observe both normal and abnormal obstetrics as it is practiced in hospitals. I also had the advantage of examining and carefully watching a large number of patients in my office during their antepartum period. I tried to correlate the size and consistency of the fetal head, the nature of the labor; whether short, spontaneous or instrumental, with the findings after a careful examination — six or eight weeks postpartum. I was soon convinced that the history of the labor, and the size of the child, very often did not coincide with the postpartum findings. Some of the most severe forms of procidentia were discovered in patients who had very easy deliveries. Again, very often few local disturbances were discovered, even after the most difficult instrumental delivery.

It seems to me that the causes for prolapse of the pelvic viscera is still not thoroughly established. Studies of the anatomy of the pelvic floor in cases of prolapse do not disclose all the etiologic factors. They simply reveal an existing condition as a result of trauma. The anatomist, during his studies, is not familiar with the obstetric history of the patient. He is unable to judge what were the mechanical factors concerned in the production of these anatomic distortions. I believe that if it were possible for the anatomist to observe the mechanical processes of a given case of labor and then study the structures of the pelvic outlet, he would reach a more definite conclusion as to the reasons why normal labor will very often cause prolapse of the pelvic viscera. To illustrate, let me quote from one of the most illuminating articles on the subject of repair of the pelvic outlet, by Haynes. He says:

> The lesions considered in this paper are produced at childbirth by the passage of the child through the parturient canal, either unassisted or aided by the use of forceps.
>
> Probably the premature application of the forceps or their faulty adjustment or ignorant use, contributes to the production of tears of the pelvic outlet. Indeed it is probable that the rarer form of rupture of the levator ani muscle close to the pelvic arch is due solely to the cutting action of the blade of the badly applied or used forceps.
>
> At birth, then, the child must pass through the pubococcygeal loop of the levator muscle, through the gap in the perineal shelf, and through the vaginal slit in the pubococcygeal hammock. . . .
>
> This passage is usually made without any material damage when the normal conditions affecting mother, child and time prevail by the gradual stretching of the structures composing the different layers. However, there may be such a disparity between the size of the child and the potential passageway or the birth so precipitate, that all the structures are torn through into the rectum or into the ischiorectal fossa. Between these two extremes there are all grades of lacerations.

We all agree as to the truth of these statements when generally applied, but the description, while

---

* Read before the Section on Obstetrics, Gynecology and Abdominal Surgery at the Sixty-Eighth Annual Session of the American Medical Association, New York, June, 1917.

comprehensive, fails to include a very essential element of the etiology of this condition, namely, a competent and complete obstetric history of the patient.

Personal observations have led me to believe that the three factors which are concerned with the production of visceral and pelvic prolapse are:

1. The construction of the bony outlet.
2. The general muscular development of the patient, especially as regards the muscles of the pelvic outlet.
3. The size of the child, particularly in cases which are overdue.

It is an established clinical fact that lacerations of the posterior pelvic segment, even when left unrepaired, do not produce prolapse of the pelvic organs. However, lacerations of the structures of the anterior portion of the pelvis will as a rule result in the prolapse of the bladder and uterus.

A study of the anatomy of the bony outlet very soon discloses the reason why, in some patients, the posterior segment is damaged, while in others the lacerations will take place in the anterior segment. The studies of Klien of the measurements of the pelvic outlet prove conclusively that the various dimensions of the bony outlet have a definite bearing on the course of labor. The relationship in the size of the anterior sagittal and the posterior sagittal line to the transverse diameter of the outlet will decide whether the head will be born at the expense of the anterior segment or of the posterior segment of the outlet. If for some reason the posterior sagittal line is contracted, the head will have to be born at the expense of the anterior segment of the bony outlet. Here the fetal head encounters the soft parts of the anterior portion of the pelvic outlet, and if the strain is too great they give way and the support of the bladder and uterus is practically removed. If, however, the anterior sagittal line is shortened and the head has to be born at the expense of the posterior pelvic segment, lacerations of the perineum will take place. A rectocele will ensue; but the actual supports of the bladder and uterus have not been interfered with.

The development of the bony pelvis is entirely neglected in the present scheme of practical medicine. The young growing girl is not given the proper care she deserves. To prepare womanhood for future motherhood requires more than passing attention. As obstetricians we must anticipate all possible defects in the development of these girls and correct them if possible.

TABLE 1.—AGE OF PATIENTS OPERATED ON

Age, Years	Number of Cases
Below 30	8
Between 30 and 40	28
Between 40 and 50	35
Between 50 and 60	21
Over 60	8
Total	100

As to the muscular development and tone, it is plain that the two intracranial glands, hypophysis and epiphysis, normally exercise a remarkable influence on the nutrition and skeletal growth. A perversion or dysfunction of one or more of the internal secretions very often may be observed at a time when proper treatment will correct it. The reason for its neglect is the ignorance of the mother. If the mothers were taught that any disturbance of metabolism in the young girl, or any apparent sexual disorder, requires attention, she would seek proper medical aid. We must ignore the conventional barriers in the treatment of the unmarried woman, as we do in the unmarried man. To modern social conditions must also be attributed an undoubted pernicious influence on childbirth. The forcing of a great number of young women to enter the industrial field early in life where they are compelled to engage in sedentary occupations prevents their physical development. This has created a large percentage of women who are unable to deliver themselves spontaneously.

The size and consistency of the fetal head surely plays an important part in the causation of pelvic lacerations and relaxations. In this instance I feel that the obstetrician is entirely to be blamed. We have no right to allow a primipara to be overdue an unreasonable time. The child grows unusually large, and the cranial bones become hard and do not mold readily. These patients are exposed to the danger of dystocia when labor sets in. It can be obviated by a timely induction of labor.

Once hernia of the pelvic outlet occurs, the problem is, What means have we at our command to correct it? Many operations have been devised; none, however, answered the purpose until the interposition operation had been perfected. This operation is of comparatively recent adoption in this country. It is only a short time that the combined abdominal vaginal operations have been performed in all of these cases. The results were poor because the anatomy of the anterior vaginal wall and that of the bladder were not taken into consideration. Usually the cystocele recurred in a very short time, and the patient felt that she was subjected to a useless operation.

We must, however, realize that the technic of this operation varies with each case. The condition of the cervix, the extent of the cystocele and the size of the body of the uterus will tend to modify the various steps in the operation. To my mind, the most important single step in this operation in any given case is to decide the exact point of fixation of the anterior wall of the uterus to the roof of the vagina. Should the uterus be fixed too high, we may have undue pressure symptoms of the neck of the bladder; and if fixed too low, the patient will always have a bearing down sensation in the vagina. For the purpose of this study I collected 100 instances in which the interposition operation was performed. Ninety of these are from the gynecologic service of Lebanon Hospital, and ten from the Jewish Maternity Hospital. I included in this series only those patients that were admitted to the hospital with the diagnosis of prolapsus uteri. Patients who suffered from lesser degrees of prolapse of the pelvic viscera, and on whom this operation has been performed, are not included in this series. I feel that in those cases other methods could possibly have been substituted.

During the childbearing period it is important that these patients should be sterilized. This is accomplished by resection of the tubes from the horns of the uterus and the stitching of the cut ends into the sides of the uterus at a point slightly lower than the original tubal opening. A few of our earlier patients were not sterilized, and in some pregnancy ensued. In all these patients labor was very complicated. The dystocia was primarily due to the high situation of the sluggishly dilating cervix in the bony pelvis. The altered axis of the uterine cavity caused the presenting part to rest against the promontory of the sacrum. The force of the uterine contractions pushed the fetal part beyond the axis of the inlet and thus prevented the part from engaging itself in the true pelvis.

A number of patients aborted before the end of the third month, as the uterus was firmly adherent anteriorly and could not rise above the brim.

Table 1 gives a statistical report of the patients operated on. The average age of the patients was 43.9 years. The youngest patient was 25 years old, the oldest 68.

The number of children the patients had was stated in eighty-three cases (Table 2).

Four were never pregnant.

The date of the birth of the last child is stated in fifty-four cases in Table 3.

The menstrual history was normal and regular in seventy-one cases.

In twenty-nine cases, menopause occurred. Relief for this condition was sought soon after the patient noticed something protruding from the vagina. Seven of these patients were operated on previously for the relief of the procidentia with little or no benefit. Forty-nine patients were treated by vaginal pessaries for a period of from two to twenty years.

In a number of patients, other pathologic conditions of the uterus and adnexa were encountered. On one patient, salpingo-oophorectomy was performed. In two cases, cystic ovaries were removed. In one case, resection of the ovary was performed. In one case, a right diseased tube was removed. In three cases, small uterine fibroids were enucleated from the uterine wall. In one case, a uterus bicornis was found.

POSTOPERATIVE COMPLICATIONS

It is interesting to note what little postoperative reaction took place in this series of cases. Most of them were fairly comfortable on the second or third day after the operation. The pain they usually suffered was that of a perineal wound. Only seven patients had marked postoperative temperature of 103 or more. Three patients had a temperature of between 102 and 103. The remaining patients had a slight rise or normal temperature. Three patients developed edema of the vulva, which cleared up at the end of a week.

Ten days after the operation one patient developed pyelitis of the right kidney, which cleared up before she left the hospital.

One patient developed temporary insanity one week after the operation. Her condition improved when she was discharged from the hospital.

One patient developed a pelvic abscess. The pus was evacuated by an abdominal incision. A vesicovaginal fistula developed which was closed about six weeks later.

Most of these patients have to be catheterized because of the inability of the bladder wall to contract on account of the extensive denudation and separation of the bladder from the vaginal wall and the anterior uterine surface. However, fourteen of these patients voided spontaneously.

The average period of time these patients were confined to bed was eighteen days. The average stay in the hospital was twenty-five days.

Finally, it is my firm belief that with the improvement in the practice of obstetrics, hernia of the pelvic viscera will be greatly diminished. Relative disproportion between the fetal head and the pelvis causing tedious and protracted labor must necessarily either stretch or lacerate the soft parts of the pelvis which eventually produces a prolapse of the uterus and the bladder. It is the duty of the obstetrician to recognize this condition sufficiently early so as to prevent its occurrence.

Furthermore, I feel that a great deal can be accomplished by carefully watching the development of the young girl; and as soon as disturbances, either of a constitutional or a local nature, are noticed, treatment must be promptly instituted, for only in that way can she be prepared for future motherhood.

62 West Eighty-Ninth Street.

ABSTRACT OF DISCUSSION

Dr. Frank L. Newton, Boston: We see many of these patients neglected, and the young women not being prepared to bear children. Pregnancy is not essential to prolapsus. One case coming under my observation is typical of many. The young woman came to our city from a neighboring state. The physician sending her said she needed hysterectomy. There was a virgin girl with prolapsed uterus who had been treated year after year with tampons and other measures. I had her examined by Dr. Fitts. When he was through I asked if he saw any necessity for doing hysterectomy. "Hysterectomy!" he said. "Why there is prolapse of the uterus, and prolapse of the stomach as well. If you take out one, why not the other?" This case illustrates, I think, the fact that the obstetric condition is not a necessary cause of prolapse. In another case, that of an older woman, married but never pregnant, there had been prolapse for years; absolutly complete procidentia, with all the parts intact. In the treatment of prolapsus uteri we must meet the conditions. If we find a large, eroded cervix in a woman who has borne a number of children, I would amputate it thoroughly, believing that here we have a field for carcinoma. The presence of a fibroid might be an indication for hysterectomy, but do not remove the ovaries and tubes even if operation is performed through the vagina. Do your pelvic plastic work yourself; such work needs an artist. Rather let your assistant carry out the abdominal procedure.

Dr. Jacob A. Ruben, Pittsburgh: Until a method gives us 100 per cent. permanent cures in prolapsus uteri, the last word has not been said on its treatment. Preparing a woman to be a mother is an enormous field in itself, which I will not touch on. I only want to call attention to the big factors underlying the causes of prolapse. It occurs primarily under two fundamental conditions: (1) the destruction or weakening of the muscular support of the pelvis; (2) the displacement of the uterus from pointing backward toward the hollow of the sacrum. In a woman who has borne two or more children, the muscles of the urogenital diaphragm are reduced to connective tissue. The levator ani alone forms the pelvic diaphragm. If in such a woman the levator muscle is torn through, we have the primary condition favoring prolapse. Physiologically and anatomically speaking, the key to all prolapse operations must be the construction of a high, muscular perineum and the replacing of the uterus and bladder in their normal positions.

Dr. Harry Aranow, New York: In a study of 4,000 or 5,000 cases I have been convinced that while a tear of the perineum may be a cause of prolapsus in some cases, in the majority of instances it is not. In a complete laceration of the perineum there is rarely a prolapse. It is the woman with a long, narrow chest and a thin abdominal wall who is likely to have prolapsus whether she has had a bad tear or not.

I have had the good fortune to have the care, in subsequent confinements, of two interposition cases in which operation was performed by Dührssen in this city. There were no complications. Of course I would not advise anybody to perform an interposition operation in a young woman. I simply mention the two cases which came under my care as house surgeon. Dr. Dührssen closed up the peritoneum very carefully and brought the uterus forward as we used to do in ventral suspension.

The operation of interposition is a very complicated procedure, with many factors to be considered. I had one case in which the woman was between 70 and 80 years of age, with complete prolapsus. The cervix was suspicious in appearance, the uterus exceedingly small. The patient was sent to me for an interposition operation. I said it was impossible. Instead I performed a Mayo vaginopelvic fixation operation, bringing the two round ligaments across, making a bridge for the bladder, and the woman made an uneventful recovery. Again, in a case of this sort, with a large heavy uterus, one cannot perform an interposition operation; nor in a very young woman who has not had children and who is anxious to have them. Interposition without sterilization is rather dangerous.

Dr. Harvey P. Jack, Hornell, N. Y.: Perhaps some day we may know more about the internal secretions and be able to administer the particular one needed. Speaking practically, however, we are faced with a young woman of from 20 to 25—several of whom I have had—with complete prolapsus. Are you going to subject that woman to hysterectomy with the consequent nervous conditions? Are you going to do an interposition operation with all its dangers? No. Amputate the cervix, shorten the round ligaments and allow that woman to go on. You have not and cannot cure her. You have given her a chance that she may develop and bear babies and be a regular woman. It is not right to allow the teaching to go out that the interposition operation ought ever to be considered. Some men may be able to do it, but when they succeed they beg the question; they do a suspension. We have no right to condemn these young women to difficult labors or the inability to have children. We must deal with the practical things until we know more of that which is not now understood. Therefore, I think this section should condemn absolutely the interposition operation. You can cure the prolapsus without it and leave the woman with a function.

Dr. Abraham J. Rongy, New York: To my mind there are two causes for prolapsus—indirect and direct. I believe that the young girl, as soon as she reaches puberty, ought to be obliged to see whether she is developing properly. I believe the question of the internal secretions will solve the matter in the near future, and that we shall be able to influence growth and development. Regarding the interposition operation, in a young woman of 25 or 26 who has had one or two children and is anxious to have more, I never advise operation. I try, rather, some form of pessary to help her, and advise that after she is through having babies such operation might be considered. In a woman who has had two or three children and who is not anxious to have more, the interposition operation comes into play and there is no operation that does the work so well. I firmly believe that intra-abdominal pressure has very little influence on prolapsus; it acts as a secondary factor when things are once relaxed and out of place. Dr. Spalding of San Francisco said that in a number of cases in the second stage of labor when the labor became tedious he separated the perineum down to the rectum in order to shorten the labor. In these cases when the head has been born at the expense of the anterior segment, I think it will be the ideal plan to separate the posterior pelvic segment and the perineum in order to allow the head to come down to the posterior part of the pelvis and not stretch the supports of the uterus.

THE INTRAVENOUS PHLORIZIN TEST*

MARTIN KROTOSZYNER, M.D.
AND
WILLIAM E. STEVENS, M.D.
SAN FRANCISCO

Phlorizin is a glucosid which was discovered by de Koninck in 1855. It is derived from the root-barks of various fruit trees, which, when brought to boiling in acid mediums, give off a glucose called phlorose, and a glycogen, the so-called phloretin.[1] Phlorizin occurs in minute and slightly pinkish crystals, and is sparingly soluble in cold water, alcohol and ether, but freely soluble in hot water from which solution it crystallizes out on cooling.[2] In 1885, von Mehring[3] found that phlorizin produces glycosuria in man. Ten years later the first statement in regard to the renal origin of phlorizin glycosuria was made by Zuntz,[4] who, after introducing cannulas into the ureters of a dog, exposed one kidney, into the renal artery of which phlorizin was injected, with the result that sugar appeared first and in greater amount from the ureter of the injected kidney. That phlorizin diabetes undoubtedly originates in the kidney was, later on, proved by Pavy, Brodie and Sian's[5] experiment. After removal of all abdominal viscera except the kidneys of a dog, phlorizin was injected, with the result that no increase in the quantity of blood sugar ensued, while the urine contained a large amount of sugar.

Less convincing as regards exact proofs were experimental investigations aiming at localization of sugar formation in the kidney. Seelig,[6] after transforming glucose in the kidney into *phenylglucosazone*, studied onset and extension of sugar formation microscopically, and from the appearance of large numbers of glucosazone needles at and around the collective tubules, he concluded that sugar excretion occurred almost entirely by means of these channels. Nussbaum,[7] who had found that the glomeruli of the frog kidney were exclusively supplied by the renal artery, concluded, from the absence of sugar in the urine after ligation of that vessel, that sugar formation occurred solely in the glomeruli. Nussbaum's findings, though, were refuted by the investigations of Adami[8] and later on by those of Beddard,[9] who discovered anastomoses between the renal artery and vein in the frog kidney, while the observations of Hellin and Spiro[10] on phlorizin sugar excretion in rabbits with experimental nephritis pointed to the epithelial cells as the principal seat of renal sugar formation. Thus the problem of exact localization of renal glycosuria, which would have cleared up many points of apparent incongruity in the application of the phlorizin test, is still awaiting its final solution.

In 1896, G. Klemperer,[11] who was the first to use phlorizin on renal lesions in man, reported absence of glycosuria in chronic nephritis after giving large doses of phlorizin internally. This method of administration was soon afterward branded as inefficacious by Magnus Levy,[12] who pointed out that phlorizin, by these means, reached the kidneys in an already broken form, and who, after hypodermic injection of the drug, observed glycosuria in various forms of pathologic kidney conditions. In 1899 Achard and Delamare,[13] on the basis of fundamental experimental investigations, stated that reduction or total absence of phlorizin glycosuria was characteristic of kidney diseases complicated by definite loss of renal parenchyma. On these facts Casper and Richter[14] based their application of the test in the form of hypodermic or intramuscular administration of the drug in conjunction with ureteral catheterization. In this way they were able to study the action of the drug separately on either kidney, and to utilize the test as a comparative index of functional renal capacity in unilateral kidney lesions. According to their statement, the phlorizin test measures the quantity of functionating renal parenchyma and, by these means, that of renal capacity, the percentage of excreted sugar corresponding to the amount of functionating parenchyma of the kidney. When these statements failed to be entirely corroborated by personal observations of various authors, and particularly after Israel's[15] demonstration of kidneys that had been found barren of phlorizin glycosuria, though possessing functionating parenchyma, Casper and Richter[14] modified their views, stating that absence of phlorizin glycosuria was significant of an advanced degree of renal incapacity, while its quantity was directly proportional to that of the functionating parenchyma of the kidney.

For the application of the test, the following technic was finally adopted: As soon as both ureters are catheterized, 2 c.c. of a 0.5 per cent. phlorizin solution (0.01 gm. of the drug) are injected hypodermically, one thigh being preferably selected as the site of injection. Only fresh solutions, never more than two weeks old, are used, and thorough dissolving of phlorizin crystals is effected by placing the phlorizin container in a water bath from which it is removed the moment the boiling point is reached. The phlorizin solution is then drawn directly from its container into the syringe and at once injected. The appearance of sugar, which normally occurs about fifteen to twenty minutes, and not later than thirty minutes after phlorizin injection, is ascertained by means of test tubes containing small amounts of heated Fehling's solution, and urine portions for quantitative sugar determination are collected during the next fifteen to thirty minutes, during which period phlorizin sugar excretion is known to be at its climax. Thus, the whole test can, in most instances, be finished in about an hour.

Inaccurate dosage, resulting from loss of water, or precipitation of crystals on cooling of the phlorizin solution, is obviated by strict adherence to these technical details, which must be carried out under trained supervision. Quantitative sugar determination is afterward done by means of Lohnstein's saccharimeter, for which only 0.5 c.c., or about 8 minims, of urine suffice; in order to insure accuracy of comparative results, three saccharimeters, two for both renal urines and the third for distilled water as control, are employed.

The literature contains either insufficient or no data concerning the technic of phlorizin application, of which we can find only brief mention in Kapsammer's[16] book. Omission of a description of technical details in textbooks and publications on the subject is, according to our experience,[17] probably responsible for the often reported failures in obtaining glycosuria, whereas we in our extensive practical work with the test have had no difficulty in that direction.

The test was soon recognized as one of our most important means for estimating relative kidney function. Israel,[18] who always maintained a skeptical attitude toward the real value of functional kidney tests, designated the test as a welcome addition to our diagnostic armamentarium, and Albarran[19] concedes to the method real usefulness. Barth[20] considers the test particularly important for the diagnosis of difficult cases, and Kapsammer[21] claims for the phlorizin test first rank among renal functional methods. Greene and Brooks[22] designate the test the most practical of functional methods, a view from which they have not departed in the latest edition of their textbook. Our own results with the test were most gratifying, and careful comparison with the results from other functional tests, especially from phenolsulphonephthalein, brought forth this statement:[23] The phlorizin, phenolsulphonephthalein and urea tests show in normal cases almost identical values for both kidneys, and exhibit in pathologic cases a striking parallelism of diminished functional values. As compared with the phlorizin method, the phenolsulphonephthalein test is subject to fewer technical errors and is less time-consuming, while the possibility of exact quantitative estimation of excreted sugar renders the phlorizin test much more reliable than the phenolsulphonephthalein test.

THE INTRAVENOUS TEST

Thus, the cumbersome technic and the length of time required for its performance appeared to be the most important objectionable features tending toward sidetracking or even eliminating the hypodermic phlorizin test in favor of the more commodious and expeditious phenolsulphonephthalein method. Success in meeting the first drawback depended obviously on the possibility of bringing the glucosid to the cystoscopic room in a vehicle in which it could be kept indefinitely in solution without, by precipitation of phlorizin crystals, losing its efficacy, and at the same time insuring the uniformity of results which generally attends the employment of phenolsulphonephthalein. For these purposes we experimented, at first, with ampules, similar to the familiar type in use for the phenolsulphonephthalein test, and containing the required amount of phlorizin in a nonprecipitating, 0.25 per cent. solution, as recently suggested by Greene.[24] However, by extensive experimentation, including comparative tests with fresh phlorizin solutions, it was found that ampule efficacy became vitiated in the course of time, four months constituting the limit, after which it was either considerably lessened or entirely extinct. While, therefore, not recommending ampule administration for general use, as involving the risk of inaccuracy, we would, nevertheless, suggest the exclusive use of this most commodious method of phlorizin application for large urologic clinics in which routine renewal of ampules could easily take place every month. For the average urologist, however, we advise the use of tablets, which we finally succeeded in devising, and which were made for us after the following formula: phlorizin, 0.01 gm., and sodium chlorid sufficient to make 0.03 gm.

Phlorizin injection by means of these tablets is a simple and expeditious procedure. The tablet is placed in the barrel of an all-glass Lüer syringe, into which, after adjustment of the needle, 2 c.c. of hot distilled water are drawn up, and injection is made as soon as, by shaking, thorough dissolving of the tablet has been effected.

Elimination of loss of time, which would remove the second obstacle to the general acceptance of the phlorizin test, appeared the more imperative, since intravenous administration of phenolsulphonephthalein had of late become established as a rapid and safe comparative functional method. It was only natural that we attempted to attain this end by the same intravenous route.

It was obviously from the start incumbent on us to establish the safety and innocuousness of this mode of phlorizin *administration*. In the literature we could find only one reference disclosing untoward results of large intravenous doses, that of Leschke,[25] who observed experimentally in rabbits grave clinical symptoms (spasms, paralysis of heart and respiration). The same author's statement that, after intravenous administration of large doses of phlorizin, an integral part of the drug was traceable in the blood of nephrectomized animals, was refuted by Glaesner and Pick,[26] who, on the basis of their repeated experimental work, insisted that no trace of enormous phlorizin quantities, up to 3.0 gm., could be found in the blood of nephrectomized animals. Neither did Biedl and Kolisch[27] nor Herszky[28] observe symptoms of kidney irritation or disagreeable by-effects and after-effects consecutive to large doses of phlorizin. For clinical purposes Albarran[19] first advocated the use of comparatively large phlorizin doses (0.02 gm.), which, later on, Casper and others[29] recommended for cases in which ordinary doses failed to produce reactive glycosuria.

---

[24] Greene: New York Med. Jour., August, 1915.

[25] Leschke: Arch. f. d. ges. Physiol. (Pflüger's), 1910, **132**, 319.

Since, therefore, small doses, which we administered in the beginning of our work, were productive only of sugar values of such minute quantities as to be practically valueless for purposes of comparative estimation, we did not hesitate to increase the dose cautiously until, by numerous tests on healthy and diseased individuals, we ascertained the fact to our full satisfaction that intravenous phlorizin administration in doses sufficiently large to insure satisfactory duration and intensity of sugar reaction was absolutely harmless and not attended by untoward sequelae. The dose of 0.01 gm. phlorizin, contained in our tablets, was found to be entirely sufficient for ordinary purposes, and even injection of the double dose, which was repeatedly made in cases in which no glycosuria was obtained after the ordinary dose, was never followed by untoward by-effects and after-effects.

Several hundred normal and pathologic cases were tested in this way in order to obtain reliable data on average time of appearance, acme of excretion, and disappearance of intravenous phlorizin glycosuria.

After laborious compilation of our cases we finally decided to utilize for tabulation case groups of equal numbers and representing, wherever feasible, different observations of the same type. By these means we were able to obtain particularly gratifying results for purposes of group comparison.

BLADDER TEST

The bladder test for determination of total renal permeability by means of intravenous phlorizin injection is performed in the following manner: The bladder is emptied by introduction of a catheter which is left in situ, and 1 cg. of phlorizin is injected into one of the arm veins. Testing for sugar is begun at once by letting a few drops of urine flow into test tubes containing a few cubic centimeters of heated Fehling's solution, until typical sugar reaction occurs. The average results of the test under normal and pathologic conditions may be gleaned from Tables 1 and 2.

In cases with normal renal permeability sugar appeared in about seven minutes and in cases with pathologic or reduced renal capacity not earlier than fifteen minutes. In both types of cases, sugar excretion was at its acme during the first fifteen minute period, was markedly reduced during the second, and was very low or had disappeared during the third period.

Our extensive work with the bladder test, which we intend to continue in the future, disclosed in many instances such inconclusive and even contradictory results as to be useless for tabulation. Many problems concerning significance of delayed appearance or entire absence of glycosuria, and relation of percentage to absolute quantity of sugar excretion, are still waiting for their solution. More conclusive evidence is particularly needed with regard to phlorizin as compared with phenolsulphonephthalein estimation. We therefore wish to limit the discussion at this time to a few facts which in the course of our investigations appeared to be fairly well settled.

In normal cases, sugar reaction generally ceased forty-five minutes after its appearance. In pathologic cases, sugar was traceable for considerably longer periods, extending to more or less than an hour, and in a few instances even to two hours. Delayed appearance, which never exceeded seventy-five minutes, did not seem to run parallel to length of sugar reaction. In a few pathologic cases the acme of excretion occurred at a later period than in the normal. In quite a number of cases of arteriosclerosis, contracted kidney, and cancer of the prostate, no sugar reaction occurred, and in only a few of them could delayed and faint sugar reaction be obtained on injection of the double dose of phlorizin. In a few of these cases, in which absence of phlorizin glycosuria persisted, initially poor values of cryoscopy and blood urea gradually approached more normal points coincident with improvement of clinical symptoms. Simultaneous phenolsulphonephthalein tests performed in this type of cases always showed delayed appearance and low, but definitely determinable, phenolsulphonephthalein values. While, on repeated testing, phlorizin sugar appearance and quantity showed such a bizarre and irregular curve as to be void of prognostic significance, phenolsulphonephthalein appearance and output, on the other hand, in the same cases assumed the characteristic curve of rising values coincident with improvement of clinical symptoms.

Equally unsatisfactory at our hands was the result of the numerously performed estimations of the total amount of phlorizin glycosuria and of the comparative determination of percentage and absolute quantity of excreted sugar, and, like Casper,[30] we do not attach to these procedures any practical value. We also agree with Blum and Prigl,[31] in refusing to accept unreservedly Kapsammer's statement that normally prompt appearance of phlorizin glycosuria is an absolute proof of normal renal capacity. But we fully endorse Greene's[32] recent statement that delayed appearance of phlorizin sugar rarely occurs in healthy individuals, and we consider persistently delayed onset of phlorizin glycosuria indicative of impairment of renal function.

In a few cases of hematuria in old prostatitics in whom the phenolsulphonephthalein test was impracticable, prompt phlorizin sugar appearance furnished a most welcome prognostic aid for operative indications. In a large number of this type of cases, on the other hand, persistent absence of glycosuria rendered the test useless.

To sum up, in the bladder test the time method of sugar appearance is of value, while quantitative methods are useless. The bladder phlorizin test is not a successful rival to the well-defined, quantitative bladder phenolsulphonephthalein test.

THE RENAL TEST

The technic of the intravenous phlorizin test for determination of comparative renal permeability is identical with that of the bladder test. As soon as bilateral ureteral catheterization is performed, phlorizin is injected and the appearance of sugar is noted on both sides. It was found that intravenous phlorizin glycosuria, when urine is collected directly from the kidneys, appeared normally about five minutes after injection. Quantitative comparative sugar determinations are then made by means of Lohnstein's saccharimeters in the previously described manner.

Tables 3 and 4 show graphically the average acme, decrease and disappearance of sugar excretion in the comparative test.

Average figures for normal cases show a striking parallelism of comparative appearance and percentage in all three tests, with differences so insignificant as to be negligible.

In the group of pathologic cases, the average of phlorizin appearance was considerably delayed on both sides, while figures for sugar percentage on both sides were somewhat smaller than those found in normal cases. Phenolsulphonephthalein, on the other hand, appeared in pathologic cases about equally as early as in normal cases, while the difference of phenolsulphonephthalein quantity amounted to almost half of that found in normal cases. The average bilateral urea values were considerably reduced as compared with those of normal cases. Averaging of values on the pathologic against those on the normal side for phlorizin and phenolsulphonephthalein gives a ratio of about 1:4, showing also for pathologic cases a fair parallelism of these tests.

[32] Greene: Hospital Bull. of the Dept. of Publ. Char. of New York, January, 1917.

Table 7 was prepared in order to ascertain which of the three tests produced the most uniform comparative figures, establishing it, by these means, as the most accurate and thus the most reliable index of relative kidney function.

In normal as well as in pathologic cases, sugar excretion was at its acme during the first fifteen minute period, was markedly reduced during the second period, and was very low or had entirely disappeared during the third period. Sugar reaction in renal urines had, as a rule, disappeared after forty-five minutes in normal and pathologic cases, and persisted to an hour or longer (seventy-eight minutes in one instance) in only a few observations of the latter type. Since the acme of intravenous phlorizin glycosuria is reached almost immediately after its appearance, and since, for comparative quantitative sugar determination with Lohnstein's saccharimeters, very small urine quantities (less than 1 c.c.) suffice, the time required for the performance of the test is, under favorable conditions, shorter than in any other functional method based on injection of a foreign substance.

For the purpose of comparing the intravenous phlorizin with other well established functional tests, the two most popular methods for comparative estimation of renal function, the phenolsulphonephthalein and urea tests, were chosen. The results of these investigations appear in Tables 5 and 6.

The ratio for comparative values of urea, phlorizin and phenolsulphonephthalein in normal cases was 104:107:187. Thus urea, an end-product of metabolism, naturally excreted by the kidneys, showed almost equal values on both sides (100:104), phlorizin, a foreign substance injected for measuring renal function, running a close second (100:107), while phenolsulphonephthalein, a dye used in the same fashion as phlorizin, showed marked discrepancy of parallelism (100:187).

The most important reason for this phenomenon is, without doubt, the unequal amount of urine which both kidneys under normal conditions may, and as every experienced cystoscopist knows, actually do secrete during the same period of time. Leaking of urine alongside the ureter catheter, temporary plugging of its lumen by mucus or a blood clot, and the often occurring unilateral reflectory auria or polyuria are additional factors in causing quantitative differences in renal urines, collected during certain time periods, as necessary for quantitative phenolsulphonephthalein determination. For the comparative phlorizin test, on the other hand, only determination of the amount of sugar excretion at a certain period of phlorizin glycosuria is needed, since it is well known that both healthy kidneys excrete simultaneously about the same amount of sugar. Tables 8 and 9 serve to illustrate this point.

In normal cases the average ratio for comparative phlorizin and phenolsulphonephthalein values was 100:110, and 100:120, respectively, while the average ratio for quantities of renal urines was 100:150. In pathologic cases the ratio for comparative phlorizin and phenolsulphonephthalein values was 100:300 and 100:170, respectively, this striking incongruity apparently being due to differences in renal urine quantities, the average of which showed a ratio of 100:270.

The wide discrepancy of the ratio of renal urine quantities between normal and pathologic cases is most decidedly due to the more frequent occurrence of reflectory unilateral polyuria in the pathologic cases, which, according to Albarran, is observed only rarely in persons with healthy kidneys.

In cases of advanced unilateral pyonephrosis (stone, tuberculous, etc.), when occasionally only a few drops can be collected from the diseased side, and in unilateral hematuria, the intravenous phlorizin test always furnished us with the desired information as regards comparative renal function, which not infrequently was either missing or unsatisfactory with other methods. In renal urines we have not observed absence of phlorizin glycosuria, which, as previously mentioned, so often occurred in application of the test on bladder urines.

The ideal aim of functional renal diagnosis tends toward determination of the absolute and largest amount of work which each kidney is able to perform. Since this ideal is not practically available at present, we must be content with methods that, like the phlorizin test, are able to demonstrate the comparative working capacity of each kidney. We hope that the improvement of the test by intravenous administration will serve to secure for it its well earned place among recognized functional methods for determination of comparative renal function. Functional kidney diagnosis is still in its infancy, and can be advanced only by critical consideration of the relative value of the various functional methods, and only in this way will survival of the fittest for practical purposes eventually result.

CONCLUSIONS

1. The intravenous phlorizin test, with our simplified technic, is a commodious and expeditious procedure.

2. In normal cases, sugar appears within seven minutes in bladder urine, and within five minutes in renal urines. The acme of sugar excretion sets in within a few minutes, and its disappearance occurs within forty-five minutes after phlorizin injection.

3. As a test for total renal permeability (bladder test) its usefulness is limited. The prompt appearance of sugar generally indicates normal function, and persistently delayed appearance is characteristic of impaired renal function. Quantitative determination of total sugar excretion is useless.

4. As a test for comparative renal function, the intravenous phlorizin test gives more accurate, and thus more reliable, results, while its technic is as simple and less time consuming than that of the phenolsulphonephthalein test.

999 Sutter Street.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. THOMAS AND BIRDSALL, AND KROTOSZYNER AND STEVENS

DR. ROBERT H. GREENE, New York: Any investigations I have carried on as regards the permeability of the kidney have been from the standpoint of the surgeon, and I have endeavored rather to keep away from the work of the physiologic chemist. I have not felt qualified for it, and I have desired to try to find things which were easy to do, and which would give me some idea as to the condition of my patient in a very short time, and whether or not the work of a physiologic chemist should be brought into any particular case.

Several years ago I tried in the wards at the hospital cryoscopy, methylene blue and phlorizin in connection with ureteral catheterization, and I found that the phlorizin test was the most practical. Later, when phenolsulphonephthalein came to the front, in a comparative series of cases, some of which were medical and some surgical, I tried to find out in a rather rough and ready way which was the most accurate, phenolsulphonephthalein, phlorizin, or the estimation of the nitrogen in the urine compared with the nitrogen in the blood. I also have carried on some little studies on indigocarmin. Indigocarmin, in my experience, is a useful test in connection with ureter catheterization, but it is not as useful in a rough and ready way because it is not elastic enough. The series of cases in which I tried phlorizin, the estimation of the nitrogen in the blood compared with the nitrogen in the urine, and the phenolsulphonephthalein test showed a marked resemblance in the results obtained. The ratio of difference between the three methods was very slight indeed. The most accurate was the estimation of the nitrogen in the blood compared with the nitrogen in the urine; but, of course, this last is work that has to be carried on by a physiologic chemist. The phlorizin test was second and the phenolsulphonephthalein third.

Dr. B. S. Barringer, New York: We all have certain reasons for certain tests. At Bellevue we use three tests, the phlorizin, the percentage urea, and the indigocarmin, for three different reasons. We believe that phlorizin—and that comes first in our estimation—gives a good quantitative estimation, an absolute ratio of what both kidneys are doing. We use the percentage urea test only in comparing the output of the two kidneys, because it gives some sort of a vague index of the relative power of each kidney to concentrate urea. We use the indigocarmin test because it is an easy test to use with the cystoscope, and we can make a diagnosis at times without ureter catheterization, simply by means of the cystoscope in the bladder.

I think when all has been said and done that we cannot depend on the functional tests alone. For instance, if we are going to perform a prostatectomy and we find the phenolsulphonephthalein is low and the blood nitrogen high, we are cautious about operating; but it does not necessarily mean that we do not operate.

Dr. Abraham Hyman, New York: We have employed most of these tests as a routine, and have practically come down to the use of indigocarmin, phenolsulphonephthalein, and the examination of the blood for urea and nitrogen retention. The phenolsulphonephthalein test we do not use in conjunction with ureteral catheterization; a two to three hour bladder specimen is examined so as to obtain an indication of the total output of both kidneys. Indigocarmin combined with ureteral catheterization has been found the most practical, simple and reliable of all the functional tests. Whereas all these tests are of value, and more so if three or four of them are applied, too much stress should not be placed on the results; patients with negative tests should not always be refused operation. During the past few years a few patients with no indigocarmin and phenolsulphonephthalein output, and a number with very slight function, have been successfully operated on for serious renal and prostatic disease. All such operations should be performed under nitrous oxid and oxygen anesthesia. Ether will often turn the balance in the wrong direction.

Dr. William F. Braasch, Rochester, Minn.: It is a difficult matter to place any definite comparative value on the phlorizin, the indigocarmin and the phenolsulphonephthalein tests. As far as phlorizin is concerned, my experience has been with the old method of subcutaneous injection, and I think Rowntree and Geraghty have shown the fallacy of these tests. The method of Dr. Krotoszyner is entirely different. It sounds very promising, and I mean to try it out thoroughly.

There is no doubt that, as a routine procedure, phenolsulphonephthalein is more accurate as an aid to differential diagnosis than indigocarmin. But I believe that indigocarmin, when injected intravenously, has its value. Not infrequently I find it valuable to employ both indigocarmin and phenolsulphonephthalein simultaneously. This would seem impossible because of the difficulty of making colorimeter tests, but the difficulty was obviated by Dr. Anders Peterson, who suggested a method by which the blue color could be removed. He found that by simply adding sodium hydroxid the blue color disappears and the colorimeter test for phenolsulphonephthalein may be continued.

Dr. Anton G. Rytina, Baltimore: I have had very little or no experience with phlorizin, a fair amount of experience with indigocarmin and quite an extensive experience with phenolsulphonephthalein. There is no question whatever that indigocarmin has a place, but for comparative values I feel that it does not compare with phenolsulphonephthalein.

Dr. Herman L. Kretschmer, Chicago: Some years ago when the phenolsulphonephthalein test was first introduced we ran a small series of cases, comparing the phenolsulphonephthalein, the indigocarmin, and the phlorizin tests. At that time we were not estimating the output of indigocarmin; we merely took the time of appearance of the blue dye and the time of appearance of the sugar. Our results were rather uniform as regards time of appearance, all three tests running quite uniform; that is, where there was a delay in time of appearance, the delay was the same for all three tests.

Because of the ease with which one could read the phenolsulphonephthalein figures, we have since then been adhering to the phenolsulphonephthalein in our work.

One of the speakers called attention to the fact that the phenolsulphonephthalein figures occasionally might be very low. I think it was Keyes a few years ago who called attention to the fact that the presence of the ureteral catheters caused a disturbance of the renal function, so that the phenolsulphonephthalein may be low and the function good. In all cases in which the phenolsulphonephthalein figures are very low (I recall one or two instances in which the output from the side which was to remain was only 2 per cent.) I make a second test later, getting the whole bladder urine.

Dr. George W. Stark, Syracuse, N. Y.: For about two years I have been using a combined functional test which I believe gives us a better insight as to the reserve power of the kidney than any other test mentioned. It is also a vascular and tubular test—the introduction of water into the circulation together with the phenolsulphonephthalein test. It is not necessarily new.

This test is based on the fact that the viscosity of the blood is absolutely constant, the urine being the varying factor. The normal figures are based on thirty normal cases. The patient is given no water for two hours previous to the test; then a pint of Saratoga Vichy is given. A catheter is left in the bladder and the urine collected for fifteen minutes. The normal case runs 20 c.c.; specific gravity about 1.024. In about half an hour after this extra water is thrown into the circulation all the reserve power of the kidney is brought into play. Under this forced excretion, normally in the third quarter there is excreted about four times the amount that we had in the first quarter. This corresponds to our experimental work on kidneys (that is, one can remove three fourths of the kidney substance and have an animal live). This hypersecretion continues for about an hour and then gradually decreases. Corresponding to this increased secretion is a lowering of the specific gravity to about 1.004 or 1.005. In other words, this shows the ability of the kidney to dilute and concentrate, and is a vascular test. In nephritis, the first quarter is somewhat less, usually under 20 c.c., while in the third quarter there may be increased elimination under forced water drinking, and very little change in the specific gravity, depending on the amount of kidney substance destroyed. Thus, if we get an elimination of 15 c.c. in the first quarter, and an elimination of 30 c.c. with but a slight change in the specific gravity, we assume that about 50 per cent. of the kidney substance is gone.

This test in conjunction with the phenolsulphonephthalein test, I believe, will give a better insight as to the extent of the injury to both the glomeruli and the tubular system of the kidney, and also as to the reserve power of the kidney.

Dr. John T. Geraghty, Baltimore: In our work with functional tests it has been our purpose, not so much to duplicate the tests that give us the same information, but to try to employ tests that give us information that we will not get from any one test. For that reason we test the excretory power of the kidney, which we do best with phenolsulphonephthalein. Indigocarmin and all these substances practically run parallel. It is simply a question of which can be read the best. They are all excreted by the same mechanism of the kidney. But we want to know, besides the excretory capacity of the kidney, any retention which may be present. It is perfectly possible for a kidney to have very markedly decreased excretion and at the same time to be able to excrete the substances that are necessary; so we make a test for retention. We select for this purpose the urea. Urea, creatinin and total nitrogen run practically proportionate. At present we are using urea because the method is simple. The concentrating power of the kidney is another function. So these three tests are all valuable, each different from the others. If there is a markedly increased excretion there will be, as a rule, retention. The concentrating power of the kidney is just as specific a function as the excretion of phenolsulphonephthalein itself, or of urea. It has been known for many years that the concentrating power of the kidney is one of the first things that suffer. There is probably only one disease in which the concentrating power is interfered with and the kidneys normal, and that is diabetes in syphilis.

Dr. Martin Krotoszyner, San Francisco: I cannot agree with Dr. Thomas' sweeping condemnation of cryoscopy, a method which, while it will never become popular among urologists on account of its difficult technic, is nevertheless one of the best tests for the determination of the functional capacity of the kidneys that we possess. On the basis of my constantly growing experience with that method, I venture the statement that in the comparatively few doubtful cases where functional tests are of paramount value, cryoscopy probably gives the most accurate prognostic information of all the tests at our command.

In closing I would once more ask you to try the intravenous phlorizin test on your own patients, as I think it possesses great advantages for comparative determination over other tests. I have not included the indigocarmin test in the tabulated comparative estimations, since that test is not applicable to quantitative determinations and thus is less flexible and less accurate than other tests. For purposes of comparative functional determinations I consider of the retention tests, the urea test, and of the excretion tests, the intravenous phlorizin test, the most commodious and accurate. Particularly in doubtful cases the simultaneous application of the comparative urea, phenolsulphonephthalein, and phlorizin tests is apt in almost every instance to give adequate data on relative kidney function.

Dr. B. A. Thomas, Philadelphia: First answering Dr. Krotoszyner, I did not mean to infer that cryoscopy was absolutely valueless, but I do say, so far as its application to the total urine and blood is concerned, that this is practically true, which is the matter of importance relative to prostatectomy. Doubtless in the experience of a few it may still be serviceable so far as individual urines are concerned, but not of any more value than the information to be obtained from the employment of phenolsulphonephthalein or indigocarmin. Unfortunately it affords no more information than the more modern tests and adds difficulty in the technic.

I agree thoroughly with what Dr. Geraghty has said, that what we want to know respecting these various tests is which is simplest, most practical and most reliable. This is the avowed object of the paper. Undoubtedly, with some the results are sufficiently uniform that there need be no particular discrimination. Frequently a second test may and should be utilized to supplement and confirm the findings of the first. Certainly any one will admit that two or more tests are of more value than a single one.

I am just as anxious to adopt the best functional kidney test as any man here, but I have not been shown by my own experience that phenolsulphonephthalein is superior to indigocarmin so far as ease of application, interpretation or reliability of results go. The advantage of indigocarmin is the simplicity of its application. In the past our experience has been largely with the employment of indigocarmin intramuscularly, although recently we have been experimenting considerably with the intravenous use of this substance, using one tenth to one fifth of the intramuscular dose. Employed in this way intramuscular pain, the only objection, comparatively, with phenolsulphonephthalein, is overcome. If merely unilateral kidney function be desired, simple cystoscopy and the observance of the onset of the dye from the respective ureters—chromo-ureteroscopy—suffices to provide the desired information. If quantitative output be desired from the respective sides, obviously the ureters must be catheterized, as in the case of any other functional test, but this requirement with indigocarmin is the exception and not the rule. Herein lies the simplicity and practicability of the indigo test. I have seen cases in which one could not introduce into the ureteral orifices other than the tips of No. 5 catheters. Under such circumstances I defy any cystoscopist to apply the phenolsulphonephthalein test unilaterally. Yet it was a simple matter to determine the functions of the respective kidneys by employing indigo. Thus, in not a few instances, it is impossible to use any test that depends on synchronous bilateral ureteral catheterization.

FACIAL PARALYSIS FOLLOWING PASTEUR ANTIRABIC TREATMENT

REPORT OF A CASE OF FACIAL DIPLEGIA WITH ONSET SEVENTY-THREE DAYS AFTER THE BEGINNING OF PROPHYLACTIC INOCULATIONS *

ROBERT L. LEVY, M.D.
BALTIMORE

A report of "treatment paralysis" following antirabic inoculations should in no sense be regarded as casting the slightest doubt on the advisability of carrying out the Pasteur treatment in cases in which it is indicated. Though hundreds of thousands of persons have, by this means, been prevented from developing an almost surely fatal disease, there are records of only 150 cases in which paralyses have followed its use. Of these patients, twenty-five died.[1]

It is desirable, however, that such cases be placed on record in order that a true estimate of their frequency may be made and, if possible, some light thrown on their obscure etiology.

The following history is of interest, first, because of the occurrence of isolated facial diplegia, an unusual form of "treatment paralysis," and, secondly, because of the remarkably long latent period between the beginning of treatment and the development of paralytic phenomena.

REPORT OF CASE

History.—A. U. N. (Med. No. 36828), a white man, aged 37, storekeeper, from Plymouth, N. C., was admitted to the medical service, Nov. 14, 1916, with paralysis of the face and pains in the head. The *family history* was unimportant. There had been no nervous diseases in the family. The general health of the patient had been good, though he was of extremely nervous temperament. At the age of 9 he had what his physician called "hemorrhagic fever," and at 21, 27 and 32, gonorrhea. He denied syphilis. He was a heavy smoker but a very moderate user of alcohol. He had been married eight years. There had been no children.

Aug. 20, 1916, he was scratched on the arm by a supposedly rabid dog, which died a few days later. The wounds were cauterized with phenol. The head of the animal was sent by express to the laboratory of the North Carolina Board of Health, and examination of the brain revealed no Negri bodies. In spite of this assurance, he became extremely apprehensive and, against the advice of his physicians, insisted on taking the Pasteur treatment, which he received at the State laboratory in Raleigh from Aug. 31 to Sept. 19, 1916. On the fourth day of treatment he began to have sensations of "something crawling under his skin," first in one place, then in another. In addition, there were "neuralgic" pains in the lumbar region and in the muscles. These symptoms had persisted. Two weeks before admission he began to feel muscular twitchings, especially in the head, neck and legs. Six days before coming to Baltimore, a severe bitemporal headache appeared, and had not been relieved by sedatives. On rising in the morning, three days before admission to the hospital, he noticed that the left side of his face was paralyzed.

---

* *From* the Medical Clinic of the Johns Hopkins Hospital.

[1] A review and critical analysis of this group of cases may be found in Remlinger: Ann. de l'Inst. Pasteur, 1905, **19**, 625. Simon: Centralbl. f. Bakteriol., Orig., 1913, **68**, 72. Fielder, F. S.: The Journal A. M. A., June 3, 1916, p. 1769. Geiger, J. C.: The Journal A. M. A., Feb. 17, 1917, p. 513.

Physical Examination.—The patient was extremely neurotic and much concerned about his condition. He frequently became lacrimose during the recital of his history. The temperature, both on admission and subsequently, was normal. He was large and well nourished. There were several pigmented scars about the left elbow, evidently the remains of his carbolized wounds.

There was complete left facial paralysis, without sensory disturbance on either the face or the tongue. There was marked lacrimation from the left eye.

The pupils reacted normally. There were no eye-muscle palsies. The eyegrounds were normal. The heart and lungs were clear. The blood pressure was 142 mm. of mercury systolic and 92 diastolic. The liver and spleen were not felt. There were *no* fibrillary twitchings; no muscular weakness or atrophy. Neurologic examination, save for the facial paralysis and slightly exaggerated deep reflexes, was negative.

A special nose, throat and ear examination revealed no abnormalities. Both cochlear and vestibular divisions of the eighth nerves were intact.

TABLE 1.—REPORTED CASES OF FACIAL PARALYSIS FOLLOWING ANTIRABIC TREATMENT

Case No.	Author	Demonstration of Rabies in Biting Animal	Age of Patient*	Facial Paralysis			Result	Remarks
				Noted				
				Days After Bite	Days After Beginning of Treatment	Extent		
1	Darkschewitz[1]	No	28	30	7	Bilateral	Recovery after 6 months	Patient alcoholic; left-sided facial paralysis appeared two days after right
2	Pfeilschmidt[2]	Patient not bitten	24	About 60 after supposed infection	24	Bilateral	Recovery in about 3 weeks	Patient syphilitic and very neurotic; did a necropsy on a rabid dog, and though uninjured, took treatment prophylactically; illness began on the eleventh day of treatment, after which no further injections were given; interval of four days between paralysis on the two sides; at time of complete diplegia, taste disturbed over anterior third of tongue
3	Borger[3]	No	?	25	24	Unilateral (right)	Well in 14 days	Illness began with sciatica on sixteenth day of treatment; injections continued; associated with the facial paralysis there was dulling of the sensation of taste
4	Jochmann[4]	Yes	30	22	18	Unilateral (right)	Well in 14 days	Illness began with sciatica on eighteenth day of treatment; still complained of paresthesias of legs on discharge from hospital
5	Hasseltine[5]	Questionable; probably yes	52	22	23	Bilateral	Recovery in 3 weeks	Paralysis developed after exposure to cold wind; patient alcoholic; interval of one day between paralysis on the two sides
6	Fielder[6]	Yes	37	53	18	Bilateral	Recovery after a few weeks	Interval of three days between paralysis on the two sides
7	Fielder[6]	Questionable	Adult	54	23	Unilateral (right)	Recovery after 4 weeks	
8	Fielder[6]	Questionable	Adult	53	31	Unilateral (right)	Recovery after 2 weeks	
9	Fielder[6]	Questionable	Adult	29	16	Unilateral	Complete recovery after 6 months	Illness began with pain and weakness in legs
10	Geiger[7]	Yes	Adult	21	17	Unilateral	Traces 9 months later	
11	Levy[8]	No	37	84	73	Bilateral	No improvement after 3 weeks in hospital; traces 9 months later	Patient very neurotic; interval of eleven days between paralysis on the two sides; at time of complete diplegia, dulling of taste over anterior two-thirds of tongue

* The patients were all men with the exception of Case 10, in which the sex is not noted.

7. Geiger: The Journal A. M. A., Feb. 17, 1917, p. 513.
8. Levy: Present report.

The urine contained no albumin, sugar or casts. Blood examination revealed: red blood cells, 4,346,000; white blood cells, 5,800; hemoglobin (Sahli), 82 per cent. The differential count was normal. The Wassermann reaction on the blood serum was negative.

November 20, the condition was unchanged. There was no further paralysis. Psychic symptoms were abating.

Lumbar puncture was performed. A clear fluid was obtained, containing eight cells and *no* excess of globulin. The Wassermann and colloidal gold reactions on the fluid were negative.

November 22, electrical examination of the facial muscles gave the following findings: Feeble response was obtained through the nerve on the left when stimulated with the faradic current. Direct stimulation of the muscles with the faradic current caused some contraction, but excitability was markedly decreased. When stimulated directly with the galvanic current, the muscles responded more slowly on the left side than on the right, and there was decreased excitability. Cathodal closing contraction was greater than anodal closing contraction.

November 27, the patient complained of stiffness of the right corner of the mouth and of an increase in the "feeling of something crawling over the body." There was slight weakness of the lower right side of the face.

November 28, the entire right side of the face was paralyzed, except for the right frontalis muscle, which contracted slightly. There was great difficulty in keeping food within the oral cavity. The expression was mask-like.

November 30, the patient was very nervous. Control of the right half of the face was now completely lost. He was having local electric treatment every other day.

December 4, the patient complained of numbness of both legs. There was no objective sensory disturbance over the body. There was marked dulling of taste sensation over the anterior two thirds of the tongue on both sides. He frequently mistook bitter for sweet, salt for sour, etc., and was much concerned about his condition. He left the hospital at his own request. He was advised to continue electrical treatment to the face at home.

A note from the patient's physician, June 25, 1917, stated that "Mr. N. is not taking any treatment now. He is very little better, judging from the appearaance of his face."

The following extracts from a letter received, Nov. 20, 1916, from Dr. C. A. Shore, director of the Laboratory of Hygiene of the North Carolina State Board of Health, furnish further interesting data:

"Mr. N. received antirabic treatment in this laboratory from August 31 to September 19, inclusive. I do not think that Mr. N. needed this treatment and I strongly advised against it. In the first place, the suspected dog did not bite him, but merely scratched his arm, on August 20. The dog died, according to Mr. N.'s statement, on August 24. The head was expressed to us; the brain was in good condition when received and the microscopic examination failed to show any Negri bodies.

"We have treated 1,620 patients in this laboratory, and from this number, excluding that of Mr. N., there has been only one case of paralysis. This developed on the fourteenth day of treatment. The patient had a complete paralysis of the lower limbs and partial paralysis of the muscles of the arms and trunk. I have never been sure whether it was a case of infantile paralysis or a paralysis resulting from the antirabic treatment. The patient was 15 years old at the time and made a complete recovery.

"The schedule of treatment which we use in this laboratory at present is that recommended by the Hygienic Laboratory of the U. S. Public Health Service."

COMMENT

A majority of cases of "treatment paralysis" have developed while the patients were receiving the injections; about one quarter, according to Simon, within seven days thereafter. Fielder cites an instance of facial paralysis with onset thirty-one days after beginning treatment, and Geiger a case of neuritis, with spasmodic contraction of the neck muscles, occurring forty-five days after the first inoculation.

In spite of the fact that in the case here reported seventy-three days elapsed between the beginning of treatment and the onset of paralysis, there can be no reasonable doubt as to the direct relationship between the antirabic therapy and the facial diplegia. Symptoms began after the fourth injection and were similar to those described in other instances of "treatment paralysis." Furthermore, the gradual development of paralysis of the right side of the face while the patient was under careful supervision in the hospital ward makes it highly unlikely that this was an example of simple Bell's palsy.

In the literature are to be found records of ten other cases of isolated facial paralysis following antirabic treatment. These are collected in the accompanying table.

An analysis of the table brings out the following points:

1. In at least three instances, the biting animal was proved nonrabic.
2. All cases in which complete data are available occurred in adult males.
3. The earliest appearance of the facial paralysis was on the seventh day, the latest, exclusive of the present case, was on the thirty-first day after beginning treatment.
4. In six cases the facial paralysis was unilateral, in five bilateral.
5. In the bilateral cases, an interval of from one to eleven days elapsed between the development of paralysis on the two sides. In no instance were both sides of the face paralyzed at onset.
6. Dulling of taste over the anterior portion of the tongue accompanied the facial paralysis in three instances.
7. Nine of the eleven patients recovered. In two cases there were traces of paralysis nine months later.
8. Of 150 reported cases of treatment paralysis, eleven, or 7.3 per cent., have been of the isolated facial variety.

The etiology of these paralyses is still in doubt. The various theories as to their causation have recently been adequately discussed by Fielder, who sums them up as follows: "There is no doubt that in most of the cases, at least, the symptoms are caused, not by street virus infection, modified by the treatment, but by the treatment itself either through the medium of fixed virus infection or through the action of a toxin, or both. In any event there must be a special idiosyncrasy on the part of the patient. Otherwise the cases would be enormously more frequent than they are." Alcoholic, syphilitic and neurotic individuals are said to be particularly susceptible.

Obviously no special form of therapy based on etiologic considerations can be carried out.

New and Nonofficial Remedies

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION. W. A. PUCKNER, SECRETARY.

BORCHERDT'S MALT SUGAR.—A mixture containing approximately maltose 87.40 per cent., dextrin 4.35 per cent., protein 4.40 per cent., ash 1.90 per cent., moisture 1.95 per cent.

Actions and Uses.—Borcherdt's malt sugar may be used where maltose is indicated in the feeding of infants, particularly in the treatment of constipation. The nutritive value of 500 Gm. of Borcherdt's malt sugar corresponds to approximately 1,985 calories.

Dosage.—It may be used in all milk mixtures in the same proportions as lactose (sugar of milk), that is, one ounce of Borcherdt's malt sugar (two tablespoonfuls) to a 20 ounce mixture.

Manufactured by The Borcherdt Malt Extract Co., Chicago. No U. S. patent. U. S. trademark No. 64467.

Borcherdt's malt sugar is prepared by the action of malt diastase on starch.

It is a yellowish-brown powder having a malt odor and a sweet taste. It is somewhat hygroscopic and very soluble in water.

If a few drops of iodine test solution be added to an aqueous solution of Borcherdt's malt sugar, a reddish-violet but not a blue color is produced.

The maltose content of Borcherdt's malt sugar is determined according to the method described in U. S. Dept. of Agric., Bureau of Chem., Bulletin No. 107, page 46.

The protein content of Borcherdt's malt sugar is calculated from the nitrogen content ($N \times 6.25$) as determined by the method described in U. S. Dept. of Agric., Bureau of Chem., Bulletin No. 107, page 5.

TYRAMINE-ROCHE — Para-Hydroxy-Phenyl-Ethyl-Amine Hydrochloride. — $OH.C_6H_4.CH_2.CH_2.NH_2.HCl$. — The hydrochloride of the base para-hydroxy-phenyl-ethyl-amine $OH.C_6H_4.CH_2.CH_2.NH_2$ obtained synthetically.

Action, Uses and Dosage.—See New and Nonofficial Remedies, 1917, p. 105, under Tyramine.

Manufactured by F. Hoffmann-La Roche & Co., Basel, Switzerland (The Hoffmann-La Roche Chemical Works, New York). No U. S. patent or trademark.

A PROBLEM CONCERNING EDIBLE FATS

"The great changes which the theories of the science of nutrition have undergone in the course of the past few years," we are reminded by Halliburton and Drummond[1] of London, "are now being rewarded by valuable practical applications of laboratory results to the great problems of animal nutrition, and the national welfare. Such a problem is that which deals with the determination of the relative value as foodstuffs of dairy butter and its numerous substitutes." These authors have accordingly undertaken to expand our knowledge in this field by a study of the nutritive value of margarins and butter substitutes with reference to their content of the fat-soluble accessory growth substance.

It deserves to be emphasized that the association of food hormones or vitamins with certain naturally occurring fats, whereby somehow they promote growth in experimental animals, was originally described by American investigators: McCollum and his associates at the University of Wisconsin, and T. B. Osborne and Lafayette Mendel in New Haven. The British investigators in reviewing the progress made in this new field of investigation, confined so largely to this country, point out that although our knowledge of the substance itself is as yet scanty, we are in possession of certain information as to its occurrence. It is present in butter,[2] butter fat,[3] butter oil,[4] egg yolk,[5] cod liver oil,[6] the lower melting point fractions of beef fat,[4] and kidney and heart fat.[7] On the other hand, it is apparently absent from the majority of oils of vegetable origin, since olive oil,[8] almond oil,[6] corn oil, sunflower seed oil, bleached cottonseed oil and linseed oil[9] were unable to replace such a fat as butter in the experimental rations used. The only animal fat as yet found to be entirely deficient in the substance is lard.[10]

The high prices that the usual household fats have demanded in recent times have brought into prominence a large number of so-called butter substitutes. The recent increase in their consumption may truly be called enormous. The higher priced margarins are usually derived from animal fats. Oleo-oil forms their basis. Vegetable oleomargarins are prepared by the utilization of some inexpensive vegetable oil, such as coconut oil, peanut oil, cottonseed oil, sesame oil or maize oil, as a basis. Liquid oils are also being converted into edible fats by the process of hydrogenation. The so-called nut butters or pastes are also replacing the more expensive butter.

The conclusions of the research by Halliburton and Drummond have been thus formulated: The fat-soluble accessory growth substance is present in beef fat and "oleo-oil," and is present in margarins prepared on such a basis. Such margarins are nutritively the equivalent of butter. Coconut oil, cottonseed oil, arachis oil and hydrogenated vegetable oils contain little or none of this accessory substance; hence margarins prepared with a basis of these fats have not an equal nutritive value to that of butter. Nut butters prepared from crushed nuts and vegetable fats are similarly not equal to butter. Lard substitutes prepared from vegetable oils are equal to lard in their nutritive value, both alike being destitute of the fat-soluble accessory substance.

Despite the importance of these researches and the unquestioned information which they furnish in harmony with many data already established by American investigators, we believe that in fairness to the many useful butter substitutes and margarins now available, a word of caution should be uttered. No one has questioned the edibility and the high degree of digestibility of essentially all of these products that have been examined as to their alimentary utilization. In this respect, like the familiar fats, they leave little to be desired. Oleomargarin has long been immune from attack on the ground of poor digestibility by its numerous frequently unfair detractors. On the other hand, the fat-soluble food hormones or vitamins are reported to be present in the leaves of green vegetables as well as in the milk, butter and eggs that are commonly found in the usual dietary. A liberal varied ration is thus likely to avert danger of lack of vitamins. We must not go to the extreme of forgetting the calorific value of fats quite aside from their content of food accessary substances.

The real danger appears in connection with the enforced rations of the poorer classes. For them, with their limited opportunities of purchase, the main conclusion of Halliburton and Drummond, that among the current products the butter substitutes that can best replace butter presumably are the margarins made of so-called "oleo-oil" from beef fat, seems more pertinent. As the London investigators remark, in ordinary times the consumption of beef dripping, which is considerable among the poor, would to a large extent supply the lacking properties of a vegetable-oil margarin. But at the present time beef itself is expensive, and the opportunities of obtaining dripping are therefore minimized. At the same time the three important foods for children (milk, butter and eggs) have risen in cost, so as to be almost prohibitive to those with slender incomes. The vegetable oil margarins still remain comparatively cheap, and the danger is that unless measures are taken to insure a proper milk supply for infants at a reasonable charge, these infants may run the risk of being fed, so far as fat is concerned, entirely on an inferior brand of margarin, destitute of the growth-promoting accessory substance. Therefore, Halliburton and Drummond conclude, it would be truer economy even for the poor to purchase smaller quantities of an oleo-oil margarin if they cannot afford the luxury of real butter.

ON KEEPING THE FAITH

In the *Deutsche medizinische Wochenschrift* for May 18, 1916, appeared a letter signed by Dr. J. Schwalbe, the editor, which has become famous. While at that time the *Wochenschrift* was coming to this office more or less regularly, that particular issue was not received; and the efforts made to secure a copy were fruitless. A copy of the letter recently came into our hands. This letter is not only one of the important historical documents of the war, but it gives a revealing flash of the spirit that must rule in Germany before that nation can be readmitted to fellowship in the world-state. The facts of the case are clear and simple. The official reason given by the German government in 1914 for declaring war on France was that French aviators had dropped bombs in the vicinity of Nürnberg before any other outbreak of hostilities. This was officially denied by the French government. And there the matter practically rested for the outside world until the publication of Schwalbe's letter in May, 1916. From this letter we quote:

> In my article "French-National Medicine" (No. 11, p. 327, line 1) I mentioned among other things—in political justification and in reply to the accusations of our enemies—that a French aviator had dropped bombs on Nürnberg prior to the declaration of war. I am apprised in a statement which Privy Councilor Riedel of Jena secured from the magistrate of Nürnberg that my memory had failed me to some extent in this matter: Not at all; I read in the newspapers of August 2, 1914, the news item that on that day, according to the statement of the officers of the Nürnberg railroad—forwarded by the semiofficial Bavarian correspondent, Hoffman—to the effect that aviators had been seen on the Nürnberg-Kissingen line of the railway and on the Nürnberg-Ansbach line, and that they had dropped bombs on the right of way. However, further correspondence between Privy Councilor Riedel and the magistrate of Nürnberg has demonstrated that this assertion, which hitherto has never been corrected, and which has been generally accepted by us as evidence of infraction of the rights of nations on the part of French aviators, is in fact erroneous. The Nürnberg magistrate, under date of April 3, 1916, writes as follows: "The army authorities here have no knowledge of any bombs having been dropped by enemy aviators on the Nürnberg-Kissingen and Nürnberg-Ansbach lines either before or since the declaration of war. All statements and news items to the contrary have been proved to be false."
>
> I consider it to be my self-evident duty to make this correction now. It frees the French of the blame which has been placed on them in consequence of this false piece of news.

In the rest of the letter Dr. Schwalbe discusses the "war state of mind," particularly the credence given by the other side to unverified rumors and accusations against the enemy. Dr. Schwalbe frankly avows in this letter that there is no evidence whatever that the Nürnberg bomb-dropping ever occurred. It is hardly conceivable, therefore, that this reason for declaring war could have been put forward by the German government in good faith. No one can look on it as other than a deliberate attempt at deception. Indulgence in fantasies is not a weakness of Prussian officials. The alleged Nürnberg bomb-dropping will take its place in human history along with the forged Ems telegram as a monstrous perversion of human ethics and fair dealing.

Germany can but reap the consequences of repeated official falsification of this sort. We in this country have not forgotten the perjured testimony, perhaps suborned, to which the German government appealed to show the presence of guns on the *Lusitania;* we have not forgotten the childish attempt to controvert the accusations made relative to the torpedoing of the *Sussex* by reproducing a "sketch" made by a submarine commander. The insincere talk of peace in December, 1916, which was later admitted by the German chancellor to have been merely a blind in order to give time for the building of more submarines, is still fresh in our minds. The discrepancy between the profession of good will and friendship by official German representatives in this country and the mesh of intrigue, bribery, arson and worse in which they were really busying themselves can never be forgotten. Where is now the *deutsche Treue?* Who can trust the word of the German government?

This untrustworthiness of official Germany is one of the outstanding facts of the present situation and is one of the principal obstacles to peace. The world in arms against Germany has been taught by Germany herself to suspect every offer of negotiation and to see a dagger concealed in every olive branch. What new trick is afoot? is the question that springs unbidden in the minds of millions whenever a responsible German official hints of peace, of compromise, of disarmament. The situation is a terrible one for humanity; it is much more terrible for the German nation. It demonstrates what some one has called the moral bankruptcy of official Germany. What can be worse for a man or for a nation than to be disbelieved, distrusted and suspected in every word and action, of bad faith? It is for this reason that a large part of the civilized world is determined to fight until a decision is reached. No other course is possible. The stake is civilization itself, the honorable intercourse of intelligent human beings.

We know well that not all Germans participate in this worship of treachery and double dealing. The Schwalbe letter is one piece of evidence that no fear of consequences can deter some bold voices from speaking out for truth and fair play. It is in some degree a credit to the fundamental integrity of the medical profession that one of the most candid and momentous confessions of error should come from one of its members. Dr. Schwalbe has kept faith with us, and we send him all honor. Every one must wish that more protests could be raised in Germany against German official trickery and official falsehood. Truth is of the essence of our scientific work, and many of us have felt keen sorrow that larger numbers of our German friends and colleagues were not keeping the scientific faith. It is the only way. Otherwise German science and German honor will become a byword and a hissing. Already men talk of "German faith" and a "German peace."

SEX HORMONES IN FETAL LIFE

From time to time reference is made in a popular way to a superstition that if twins are of opposite sexes, the female is sterile. How unfounded this belief is in the case of human twins appears from an old investigation of Simpson in Edinburgh. He investigated the family history of 123 married women born twin to males, of whom 112 had families and eleven had none. The proportion of childless marriages was not greater than in the general population. It may be that the mistaken notion is derived by analogy from what is known to be the case among cattle. There the facts are different. In about nine tenths of different-sexed twins the female is sterile. Such females among cattle are commonly known as freemartins. The phenomenon is not known to occur among other species.

Lillie[1] of the University of Chicago has furnished a highly probable explanation of this peculiarity of sterility of the female of different sexed twins. It has been assumed by some that the freemartin is merely a modified male. The evidence now furnished by Lillie indicates with more than probability that the *freemartin is by heredity a true female.* He has concluded that it is modified by the sex hormones of the *male twin, which circulate in both individuals during fetal life owing to secondary fusion of the chorions* and anastomosis of the fetal circulation of the two individuals.

The question naturally arises as to why there is not a reciprocal relation between two opposite sexed twins. If their blood intermixes why do not the sex hormones of the female exert an effect to alter the male? The answer is presumably to be found in the earlier differentiation of the sex glands of the male in the development of the individuals so that they can exert an influence through the liberation of hormones before the ovary begins to develop. The previous differentiation of the testis thus leads to suppression of specific ovarian tissue from the beginning, in the female; hence the limitation of the freemartin condition to that sex.

The sterility of the female of two-sexed twins—a phenomenon due to the circulation of the blood of the male twin in the female, owing to peculiar fetal vascular connections in twin pregnancies—is limited to cattle because these anatomic conditions are rarely if ever duplicated in other species. Fusions of adjacent chorions are occasionally found in multiparous animals; but there are no vascular connections. In some mammals the conditions of placentation are such as to prohibit chorionic fusion. The problem arises as to how it happens that the sex hormones of the mother, which numerous facts indicate to be responsible for secondary sexual characters,[2] do not affect the reproductive system of the unborn sons. Lillie concludes that the embryo is in some way protected from these hormones circulating in the maternal blood. Either, he says, there is a cessation of production of sex hormones during fetal life, or they are neutralized in some way, or the placenta is impervious to them. The last supposition seems most probable to Lillie.

There is a broad biologic import to these studies. In the lower forms of life, reversibility of sex has been experimentally demonstrated. In the freemartin, a hereditary female, the internal organs of reproduction are usually predominantly male in character, and the external organs usually of the female type. Evidently the male hormones that reach the female fetus do not cause the development of any structure that is not represented embryologically in the normal female; the hormones act in this case merely by inhibition or stimulation of normal embryonic rudiments. To quote Professor Lillie:

> For their proper evaluation the results concerning the freemartin should be associated with other studies indicating that

zygotic determination of sex is not irreversible predestination, but a quantitative overbalance in the direction of one sex or the other. Sex determination is controllable within variable limits in certain groups, to which mammals must be added as a result of the present study. To determine the means, limits and subsequent results of such control is now one of the most important tasks of biology.

CERTIFIED MILK AND THE BACILLUS OF CONTAGIOUS ABORTION

Certified milk is the term applied to "milk produced under sanitary conditions of exceptional excellence, by the most painstaking methods and under constant supervision and inspection of a medical milk commission." The certified milk of the present day is essentially the outcome of the efforts of the medical profession, and the establishment of such a grade of food product from the dairy has unquestionably had a most wholesome influence for the betterment of the general milk supply and the raising of its sanitary quality. As the herds of cattle involved are systematically subjected to a tuberculin test, and the certified milk that the nontuberculous cows produce is expected to contain less than 10,000 bacteria per cubic centimeter when delivered, such milk has come to have the reputation of being safe even when used in the raw state.

In an investigation lately conducted at the University of California Medical School by Fleischner and Meyer,[1] attention has been directed to the adequacy of the safeguards against the dissemination of bovine tuberculosis as they have been introduced into the highly organized scheme of dairy hygiene fostered by the medical milk commissions. The presence of tubercle bacilli in unheated market milk of the usual quality has often been demonstrated. In the certified milk produced in the San Francisco Bay regions, tubercle bacilli are not present in sufficient number to infect guinea-pigs, the usual test subject, with tuberculosis. If this observation proves to be of more general validity, Fleischner and Meyer maintain that there is no necessity for pasteurizing certified milk on account of any danger that it may possess as a disseminator of bovine tuberculosis to infants.

Quite unexpectedly, however, the California investigators found that *Bacillus abortus*, which is held responsible for infectious abortion observed among cattle, is, for practical purposes, always present in the certified milk produced in the San Francisco Bay regions. Fleischner and Meyer believe it to be not unlikely that in many previous milk tests for tubercle bacilli, the anatomic lesions of bovine abortion disease in the guinea-pig were mistaken for tuberculosis. Furthermore, they say, if *B. abortus* is present in certified milk to the extent evident from these experiments, it is difficult to consider it pathogenic for infants, without, so far as is known, ever having produced recognizable lesions on postmortem examination.

Even if the consensus of the scanty evidence now available is against any probable pathogenicity of *B. abortus* of cattle for man, it must be admitted that there are too few studies on the possible significance of this organism from the standpoint of human health. The California investigations are likely to start renewed consideration of the status of unpasteurized certified milk. There are chapters relative to milk hygiene that seem never to be closed. Revision is, however, the sign of progress toward the best that present day knowledge affords.

Current Comment

THE DEVELOPMENT OF THE MAMMARY GLAND

That the growth of the mammary gland during pregnancy is determined by some form of chemical stimulation rather than through nervous influence seems to be established beyond question. Precisely where the effective agent or the specific hormone that induces growth of the tissue is produced has been somewhat debated. It is essential to distinguish clearly between the developmental changes in the mammary gland, on the one hand, and the factors leading to secretion, on the other. Thus it has been suggested that the stimulus which results in the production of milk is in reality inhibitory in character. By preventing secretion it is assumed to permit the continued growth of the glandular tissue. Lane-Claypon and Starling,[1] whose pioneer investigation in this field is well known, thought that the growth of the mammary gland in their experimental animals was due to the presence of the fetus. The evidence now seems to be conclusive that the corpus luteum—the tissue produced in the ovary as the result of the discharge of an ovum—exerts the influence responsible for the growth changes in the mammary gland during the first part of pregnancy.[2] But since the gland continues to develop throughout the period of pregnancy, while it has been believed that the corpus luteum tends to undergo regressive changes before parturition, the explanation for the later developmental progress has been in question. Ancel and Bouin attributed it to a hormone produced by a special tissue, the myometrial gland, reputed to make its appearance in the wall of the uterus at the site of implantation of the placenta and last until the end of pregnancy. The possibility that the placenta might be a potent source of the growth stimulus has also been considered. The latest experiments of Captain Hammond at the School of Agriculture in Cambridge, England,[3] indicate that in rabbits, at least, the corpus luteum, contrary to the generally accepted opinion, is active during the second half of pregnancy, and that it controls the entire development of the mammary gland. There is a definite correlation between the development of the corpus luteum and the increase in weight of the mammary gland. Indirectly the fetus plays some part, since it appears to be responsible for the continued performance of the corpus luteum. The reputed significance of the myometrial glands is lost in view of their inconstant occurrence. Experiments in which the fetuses were removed without destruction of the maternal placenta have shown among others that the latter is not the source of the stimulus which causes the glandular phase of the mammary gland. There is no evidence that the secretory stage is due to anything different from that which causes the growth changes. Apparently, Hammond says, the secretion of milk results whenever the influence causing the glandular growth is removed or lessened in amount. In this case, then, milk secretion takes place in correlation with the involution of the corpus luteum.

TAXES—JUST AND UNJUST

In war it is essential that every citizen give freely of his time and strength to the cause. It is also his duty to pay the taxes that war renders necessary, cheerfully and promptly, without any thought of evasion. Nevertheless, if by error in judgment, or error not intended, there is legislation that results in inequality in taxation, so that one individual is burdened while another in practically the same condition escapes, it is proper to urge on our legislators the need of correction. As some of our readers know, Section 209 of the present war tax law directs that in addition to the income taxes and surtaxes, there shall be an additional tax of 8 per cent. in the case of professional men after an exemption of $6,000. The result is a manifest injustice in that a physician who has no other income but that produced by his own earnest efforts pays this tax of 8 per cent., in addition to the normal income and surtax, whereas the youth who has inherited from his father an amount of money that enables him to live in ease on the interest derived therefrom is not so taxed. Section 209 is a penalty on brains and hard work, and favors inherited wealth. Senators and representatives have acknowledged that it was slipped in without its effects being appreciated or without their knowledge, as a last minute addition after the final conference, and that at the coming session in December an effort will be made to correct or amend Section 209. When Congress convenes, an endeavor will be made to eliminate this "joker" from the law. Physicians whose gross annual income exceeds $6,000 are, of course, interested in this proposition, and should bring influence to bear on their congressmen to get a bad law rescinded.

MEDICAL PIONEERS OF KENTUCKY

The issue of the *Kentucky Medical Journal* for November 1 is an historical number, edited by Dr. J. N. McCormack. "Recognizing that history, after all, is little more than a succession and tactful combination of selected biographies," the editor has undertaken the "task of collecting and preserving in a somewhat permanent form such still available data . . . as might . . . be useful as the foundation of such a history of that day as would be worthy of the actors whose momentous deeds it recorded." The volume is largely a compilation of biographic sketches recording the professional work of the several subjects and is grouped under the following heads: the McDowell Group, the Transylvania University Group, the University of Louisville Group, and the General Kentucky Group. It is profusely illustrated with portraits of Kentucky physicians, many of whom gained recognition as leaders in the American medical profession. These memoirs of physicians who accomplished so much for scientific medicine in the Middle West under inadequate facilities must be an inspiration for the present and future research work in both the art and the science of medicine. This particular issue of the *Kentucky Medical Journal* contains over one hundred and seventy pages and is deserving of the highest praise not alone from an editorial point of view, but also from its general mechanical and typographic arrangement and make-up. Kentucky has set an example for other state associations to follow.

Effect of High Prices on the Consumption of Milk.—To determine to what extent the high price of milk had affected its consumption among the children of the poor, an investigation was made in October under the joint auspices of the Department of Health, the New York Association for Improving the Condition of the Poor and a Committee on Milk appointed by the mayor, among 2,200 New York families each containing from two to six children, or 12,439 individuals in all. Of these 4,467 were adults and 5,438 were children under 6 years. The total amount of milk purchased by these families was 3,193 quarts as against 4,797 quarts a year ago. This decrease was partially offset by the daily purchase of 141 tins of condensed milk. The amount of milk which physiologists and pediatrists have estimated as the normal amount required by all of the persons considered is 8,194 quarts. It was found in the investigation that 121 families were getting more milk than a year ago, 599 families were getting the same amount, 1,480 families were getting less, and 420 families were now getting more condensed milk. Of the families getting less milk, over half (969) were getting from 25 to 50 per cent. less. Two thousand one hundred and forty-eight children under 6 years of age were drinking tea and coffee. The foregoing is set forth in the *Weekly Bulletin* of the Department of Health, Nov. 3, 1917. The commission appointed by Mayor Mitchel to investigate and report on the possibility of preventing a further increase in the price, or of lowering the present high price, which was 14 cents as against 9 cents a year ago, in their representations to the dairymen's league made the following statements (same publication): 1. The present high cost of milk has reduced the total supply of the city by approximately 25 per cent. 2. In many sections of the city it has reduced the quantity of milk used as much as 50 per cent. 3. In some sections of the city the quantity used by infants and children has been reduced below the minimum which the best medical science considers necessary for the maintenance of health. 4. There has been a recent increase in infant mortality which the health department believes to be due to a decreased use of high grade milk.

Medical Mobilization and the War

MEDICAL MISSIONS FOR ROUMANIA

A medical mission under command of Col. Walter D. McCaw, Manila, P. I., M. C., U. S. Army, consisting of medical officers and nurses, has been organized by the Surgeon-General for service in Roumanian hospitals. Colonel McCaw will report to the American minister at Jassy.

According to the *British Medical Journal,* a Japanese medical corps of 100 men has gone to Roumania to help control the epidemic of typhus in that country, with headquarters at Jassy.

AMERICAN SPAS AND THE WAR

In England and France the military authorities are making use of the hydrologic resources of the spas of those countries in the treatment of convalescent soldiers. Dr. Guy Hinsdale has called attention to the extensive use of these spas by the English and the French, and suggests that an inventory of American hydrologic resources should be taken.

THE CARREL-DAKIN TREATMENT OF WOUNDS

Report of Special Committee Appointed by the Director-General of the British Army Medical Services

A committee appointed by the director-general of the British Army Medical Services for the purpose of investigating and reporting on the Carrel-Dakin treatment of wounds has made its report (*British Medical Journal,* 1917, **2,** 597). The hospitals visited were Carrel's, which at the time of the visit was under the surgical care of Guillot; the clinics of Tuffier and Chutro in Paris; the American Ambulance in Paris, and Mrs. Depew's Hospital at Annel. In Carrel's, Tuffier's and Chutro's clinics, only Dakin's fluid is used. In the Annel Hospital, three fluids are used with Carrel's tubes —Dakin's fluid, eusol[1] and ether. The committee was assured that good results were obtained from each of them. The committee points out that it is evident that in estimating the value of the Carrel-Dakin treatment, care must be taken to appraise quite separately the method of applying the antiseptic and the antiseptic employed. While convinced that the use of Carrel's tubes, as the committee saw them employed, is a very valuable means of applying an antiseptic fluid to a wound, the committee is not satisfied that Dakin's fluid is markedly superior to eusol, and was prepared to find that other antiseptics can be used with advantage by the Carrel method.

The results of the Carrel-Dakin treatment, as seen in a large series of unselected cases, were remarkably good. The most striking evidence of the value of the treatment seen by the committee was a printed notice put up in a prominent place in Tuffier's wards, said to be the expression of his own opinion after a considerable experience of the Carrel-Dakin treatment. The notice is as follows:

"Tout blessé qui suppure a le droit d'en demander la raison a son chirurgien" (every patient whose wounds suppurate has the right to demand an explanation of his surgeon).

The committee is of the opinion that the Carrel-Dakin method of treatment, if carried out thoroughly, is full of promise, and believes that it will (1) diminish the dangers incidental to sepsis, including secondary hemorrhage; (2) hasten the patient's convalescence; (3) lessen the liability to stiff joints and cicatricial deformities; (4) enable the patients to leave the hospital with better general health than they otherwise might, and that (5) when secondary operations become necessary, these operations are more likely to be free from septic complications than when some other system of primary treatment has been adopted.

NEWS OF BASE HOSPITALS IN FRANCE

Notes of Interest Gathered During a Tour of Several British and French Hospitals

[In a personal note accompanying this communication Captain Hirschman says: "I am sending herewith a report of observations I made while on special detail in one of the busy districts of France. It was considered of sufficient interest to the Chief Surgeon, Lines of Communication, American Expeditionary Forces, France, to have it sent to, and read by, the Medical Staff of all the base hospitals. . . . We of the Harper Hospital Unit, of Detroit (Base Hospital No. 17), are fortunately situated in an old city full of historical interest. The main building of our hospital is an old seminary building, which adapts itself very readily to hospital purposes. We are enlarging our hospital to 1,200 bed capacity."]

In all the hospitals the Carrel method of using hypochlorites is universally employed in the treatment of all infected wounds, and also as a prophylactic treatment for all wounds of which the slightest doubt is entertained. Punctured wounds are converted into incised wounds, all badly bruised tissue is excised, and Carrel-Dakin solution is started at once. Plenty of rubber tubing must be used, and the skin surfaces around the wounds well protected by gauze saturated with petrolatum. It must be remembered that the Carrel-Dakin tubes are used to bring the solution in contact with every portion of the wound, and are not used in any sense as drainage tubes. The solution is used at room temperature and not by the so-called drop method.

Bacterial counts are made daily or every other day until the number of micro-organisms is reduced to one half to a field. When this time arrives, physiologic sodium chlorid solution, or artificial serum, as the French call it, may be substituted for the Carrel-Dakin solution. In some cases the wound is sutured at this time with satisfactory results. Some British hospitals use an iodoform-bismuth petrolatum paste as a dressing following the Carrel-Dakin treatment.

HOSPITAL TRAINS

Some very beautiful examples of color photography and ordinary photography with the use of the yellow filter were observed. Very few end-results were seen because of the necessity of evacuating the hospitals as soon as patients can be transported comfortably to England for convalescence.

The hospital trains as used by the British are models of completeness and sanitary excellence. They consist of passenger coaches of the finest type, more like the American car than anything else seen on this side of the water. The ordinary hospital train consists of one car with compartments for the commanding officer, his one or two assistants and the nursing sisters, along with mess and bathing facilities for each group, an operating and dressing room car, a car for baggage and supplies, a varying number of ordinary coaches for the ambulant patients, and coaches provided with racks on which the stretchers containing the recumbent patients are placed. These racks are so constructed that three tiers of stretchers can be accommodated on each side of the aisle.

One of these hospital trains will accommodate as many as 500 or 600 patients. A patient is never removed from the stretcher from the time he is placed in the ambulance at the evacuating point until his reception on the hospital ship, and in some cases until his arrival at the convalescent hospital in England. The skill, ease and rapidity with which patients are handled is remarkable, and the happy expressions on the faces of even the severely wounded and seriously ill is the best evidence of the satisfactory manner in which the transportation of the sick and wounded is being carried out.

The hospital ships are equipped in much the same manner as the hospital trains, large wards taking the places of the rack cars.

The Carrel-Dakin treatment is carried on in hospital trains and ships just as carefully as in stationary hospitals. Minor operations and dressings are done with great success in the operating rooms of both classes of invalid transport.

The majority of the cases in the hospitals in this district are medical rather than surgical, the proportion being about 60:40 per cent. The average stay of the patient in the hospital is from eight to ten days. The principal diseases found are trench fever, pyrexia (of unknown origin), pneumonia, pleurisy, gas infection, gastro-enteric infections, kidney and heart diseases, and other diseases as met in civil practice.

SURGICAL NOTES

One thing that has impressed the observer in his tour of the hospitals has been the fine team work between the various medical officers as observed everywhere, and nowhere to better advantage than in British General Hospital No. 1, which is manned by Americans. The American base hospital unit as organized at present has a well balanced medical staff representing all of the specialties. This has been taken advantage of in the treatment of all patients, so that each specialist is enabled to give his best efforts to those to whom his services are of the greatest value, and to bear his share of the routine ward work, which is cared for by all.

---

[1] Eusol (Edinburgh University solution) is an acid solution of hypochlorites prepared by shaking 12.5 gm. of chlorinated lime, and 12.5 gm. of powdered boric acid with 1 liter of water. The mixture is allowed to stand for some hours, and is then filtered.—Useful Drugs, 1916, p. 44.

While our hospital units were organized primarily to care for 500 patients, unusually heavy convoys have increased the number of patients to over twice the original capacity. Experience has proved that the number of medical officers, from twenty-six to twenty-eight, is sufficient even for the increased number of patients cared for at times; but both the nursing and the enlisted staffs are inadequate to the demands thrown on them. Instead of sixty-five nurses, 100 would be the proper number to give adequate nursing service with justice both to patient and to nurse, while fifty additional enlisted men would be able to care for the extra 500 patients without difficulty.

The utilization of railroad stations, hotels and other large buildings has worked out in a very satisfactory manner. Most of the buildings seen by the observer have been wonderfully well adapted to hospital purposes. Extra ward space has been provided by the building of temporary huts accommodating from twenty to forty patients each.

Separate hospital buildings are provided for sick and injured officers, and also in a large center like Havre a special hospital is operated for sick nursing sisters.

Isolation hospitals and convalescent camps also serve their useful needs, and a new convalescent hospital capable, I understand, of accommodating up to 40,000 patients, is now being built by the British at ———.

ORGANIZATION

A surgical ward containing from forty to eighty beds is in charge of a senior and a junior medical officer and a supervising nurse with three assistants. The usual hours for nurses' duty are from 7:30 a. m. to 8 p. m. with a half hour off for noon meal, breakfast being taken before going on duty and dinner when coming off duty in the evening. If work is light, an hour for recreation is allowed in the latter part of the afternoon. In British General Hospital No. 1 at ———, a number of nurses' aides, having from one to two years' experience, are utilized and give great satisfaction. They do everything for the patients except surgical dressings and administration of medicines, and relieve the graduate nurses of a great deal of work, thus allowing them to assist the surgeons in making surgical dressings.

When a convoy arrives from the front, patients are taken from the hospital train to the hospital usually in motor ambulances, are sorted out according to their field diagnosis cards, and are allowed to rest for a couple of hours. Then each patient is bathed carefully, dressed, and a more definite diagnosis made. Unless operation or the roentgen ray is urgent, these are put off until the following day. All patients receive a preliminary dose of 500 units of antitetanic serum at the casualty clearing station, and a second dose in the hospital in from six to ten days after the first injection.

A wound, whether sutured or not, which presents local tenderness and infiltration and is not necessarily edematous and visibly infected, is incised at once and the incision carried through fascia or aponeurosis so as to allow the muscle to bulge freely. Carrel-Dakin treatment is started at once as a prophylactic measure. Many wounds of large size are not treated thus, but are exposed to sunlight with great success. A large shell wound of the thigh or buttock, for instance, will be given all the sunlight the patient can stand by moving his cot to the most exposed location, shading his face and covering the part with mosquito bar. This treatment is also very efficacious for extensive burns.

In the dressing of painful wounds, a very valuable method of anesthetizing the patient is used without danger, even though required daily. The formula of the anesthetic is: ethyl chlorid, 5 c.c.; chloroform, 1 c.c.; ether, 24 c.c. A piece of flannel cloth is saturated with the entire amount and placed over the patient's face. This is covered with another piece of flannel, and this in turn is covered with oil silk containing a small aperture, fitting over the nostrils. This is tied around the patient's face with a bit of tape or rubber tubing. The anesthesia produced will last for ten minutes, and the dressing can be started on the second breath. This anesthesia is apparently devoid of danger, is not accompanied by unpleasant complications, is followed by no deleterious after-effects, and is welcomed by the patient.

It has been found of great value, although the officer of the day attends to all emergencies, to have him call the physician or surgeon in charge of the ward if a severe hemorrhage or unusual emergency arises at night. The officer of the day occupies a special bedroom at night which is known to every one so that no time is lost in reaching him if needed.

In all of the hospitals visited, both French and English, the supply of anesthetics, instruments and paraphernalia generally seemed to be ample.

The food in all hospitals was of good variety, the quantity ample, and its preparation very satisfactory.

In hospitals not housed in permanent buildings, both wooden huts and canvas tents of various types are utilized. It has been observed that canvas tents with double walls allowing an air space of from 4 to 6 inches between are much warmer than wooden huts.

DISPOSAL OF REFUSE

It was noted with interest that in the disposal of garbage and kitchen refuse, every effort is made to save all of the fats and drippings. As these are separated from the rest of the garbage, they are run into tanks containing water which is slowly and constantly changing. The fat rises to the surface of the water and at intervals is skimmed off, gathered up and saved for glycerin making. The rest of the garbage is incinerated.

In some places large settling pits are dug, and are filled with old tin cans which have been previously flamed. Wash water and other liquid refuse from laundries and kitchens are allowed to drain into the ground through these pits.

Nothing has been observed in any of the hospitals, barracks or camps visited which in any way can compare with the latrines as devised and used by the American Army. Incineration of the feces is the method of disposal, and while it in itself is undoubtedly very satisfactory, it involves an unnecessary amount of labor in the cleaning out of latrine cans and the conveying of this material to the incinerators. A disagreeable and unhealthy stench is produced during the whole process, which is entirely obviated by the method of the American Army. The same criticism applies to urinals. The urinals observed usually consisted of ordinary galvanized iron or tin troughs which receive no other attention than an occasional flushing.

DELOUSING STATIONS

The delousing stations, which are important adjuncts of every hospital, consist of portable steam sterilizing outfits into which the clothing of new patients is placed. All clothes are subjected to steam sterilization at 215 F. for from one hour to an hour and a quarter, and then allowed to dry out in the sterilizer for forty minutes thereafter.

Some hospitals have been achieving very satisfactory results in the treatment of infected wounds, particularly of joints and sinuses, by the injection of eusol, which is a solution of chlorinated soda somewhat similar to the Carrel-Dakin solution but of greater germicidal power. This is injected directly into the diseased area every two hours or through tubes, the same as the Carrel-Dakin solution.

In some institutions ether was the anesthetic of choice, while in others nitrous oxid and oxygen was the anesthetic most frequent used.

SUTURING OF WOUNDS

One thing noted by the observer has been the amount of unnecessary surgery and after-treatment as well as undue prolongation of hospital confinement and subsequent unnecessary absence from the line, a large part of which can be avoided. This is due to too much unnecessary suturing of wounds in the casualty clearing stations.

While it is recognized that hemorrhage must be checked, sometimes by ligature and again by suture, immediate closure of wounds in these stations is to be severely condemned. Many infected wounds seen by the observer have required immediate reopening, removal of sutures and Carrel or similar treatment, because of the stitching done in the casualty clearing stations.

A great deal of unnecessary time and labor is spent in work which only has to be undone and which really is to the detriment of the patient. In many cases wounds really should be enlarged and packed instead of closed in order to afford opportunity for cleansing and drainage. The minimum amount of suturing consistent with safety from hemorrhage should be employed. A further treatment of the wound should be left to the hospitals farther back from the line. As suturing takes time and material, this work is not only unnecessary but also harmful, and is a break in the chain of efficiency which should not obtain in our system of medical relief.

BRITISH GENERAL HOSPITAL FOR VENEREAL DISEASES

British General Hospital No. 39 is a large institution of over 3,000 beds devoted entirely to the treatment of syphilis, gonorrhea and chanchroid. Four hundred of these beds are for officers. This is one of four similar hospitals conducted by the Royal Army Medical Corps for the treatment of these diseases. It is situated in the suburbs of ——— amid beautiful surroundings. It consists of huts, bungalows and tentage, the streets are well paved and perfectly drained, rows of shrubs and flowering plants line these streets, and has everything conducive to the comfort of the inmates.

A well equipped operating room with special wards for surgical patients is one of the many good features of the institution. The salvarsan room contains six tables with arm rests, irrigator stands, etc., and the intravenous treatment is frequently given to six patients at the same time. The intramuscular injection of neosalvarsan is used in a great many more cases than the intravenous—of old salvarsan—and with most excellent results.

The number of syphilis patients treated in this hospital since Jan. 1, 1915, was 11,500. To these patients were administered over 89,000 injections of salvarsan and neosalvarsan. The number of cases of dermatitis and jaundice developing was only 152, and the number of deaths occurring in this whole series was either ten or eleven.

As a result of the treatment in this hospital, the number of troops returned to the front effective for duty was over 11,000; while the number invalided to England in the last year was only seventy, which is but a fraction of the number heretofore sent home.

The French and English preparations similar to neosalvarsan and old salvarsan have proved fully as efficacious, and the standard treatment for syphilis in this hospital consists in the combination of the intramuscular injection of a suspension of metallic mercury in sterile oil and water in conjunction with the intramuscular injection of neosalvarsan, as well as the intravenous use of old salvarsan.

The Wassermann test is used in all cases before the men return to the front; but patients symptomatically cured even though exhibiting a positive Wassermann reaction are nevertheless returned to the front because they are again effective for the full military duty.

The proportion of cases of syphilis to gonorrhea is 1:3. Gonorrhea here as elsewhere has proved more resistant to treatment than syphilis. The recent cases are treated with a 1:4,000 solution of potassium permanganate, used in the ordinary way as urethral irrigations. The cases of long standing are being treated with gonococcus vaccine, which is made in the hospital laboratory, and also by means of urethral bougies impregnated with any one of the various salts commonly used for the purpose.

On inquiry as to why venereal prophylaxis was not carried out in the British Army as it is in the American, I was informed that public sentiment in Great Britain had not as yet been educated up to the same point as in America, and that the frank discussion of these matters was still more or less taboo. One of the medical officers in charge made the statement that he feared that a soldier contracting a venereal disease and not reporting for prophylactic treatment, as required in our army, would by endeavoring to conceal his condition so neglect himself as to become a more difficult case when concealment was finally no longer possible.

The other three hospitals devoted entirely to this purpose and conducted by the British Army are just as busy as No. 39, so that the enormous number of noneffectives caused by prevalence of venereal disease can be easily demonstrated.

As the startling prevalence of venereal diseases in France has been demonstrated by the experience of the armies stationed here, it is hoped that in spite of our excellent measures of prophylaxis the American expeditionary force will have sufficient hospitals in readiness for the treatment of such of our forces as become infected in spite of all our preventive measures.

THE MICRO-ORGANISM SUPPOSED TO BE RESPONSIBLE FOR SO-CALLED TRENCH FEVER

The most interesting thing observed during my several visits to British General Hospital No. 1 has been the research work being carried on in the hospital laboratory by Captain Pappenheim, M. R. C.

He has isolated a disk-like organism from a number of patients suffering from trench fever, and has grown this organism on artificial mediums as well as on blood serum.

It is found in the periosteum and around the blood vessels of the tibialis anticus muscle but not in the muscle fibers itself, and also is easily found in the stomach walls of the body louse.

The organism, as stated above, is disk-shaped, is about one-thirtieth to one-fortieth the size of a red blood corpuscle, and is best observed when overlying the corpuscle. It stains with the Wright-Giemsa stain (heated), and also with hematoxylin after being fixed with Zenker's solution. It will also stain with hot Azure 2, Ziehl-Neelsen (without much discolorization) and hot ordinary weak carbol-fuchsin. It will not stain with eosin or Gram's stain except faintly. The organisms are evidently protoplasm.

This organism is cultivated by dropping a small fragment of periosteum removed from the tibia into a slant agar culture tube. After four days' incubation a dark cottony cloudiness will appear just below the junction of the agar and the water of condensation. The organism becomes encapsulated in eight days, and appears in a sort of hanging drop formation in the tube. Under the high power, the disk when superimposed on a red blood corpuscle looks not unlike a small crescent-shaped nucleus occupying about one fifth of the area of the disk, the balance being very faintly outlined but nevertheless visible. As many as six will be found in a field. In the organisms which are evidently older, the so-called nucleus appears to be split into a number of sections of irregular shape. These older organisms are distinctly encapsulated.

As stated above, the organism has been found in every case of trench fever in the periosteum of the tibialis anticus, where the pain of the disease is located. It has also been found in the blood in a few cases. Efforts are now being made to perfect the technic of blood culture in this work. The organism has been found with great ease also in the body louse as found on patients returning from the front, and has best been demonstrated in sagittal sections of the stomach wall of the louse.

A preliminary report has been prepared, and it is expected this will be published in a forthcoming number of the *British Medical Journal.*

The work is being carried on in a painstaking manner by Captain Pappenheim and his associates, and it is hoped that other hospital units will find it of sufficient interest to investigate these findings and prove or disprove the connection of this new organism with so-called trench fever.

Louis J. Hirschman, Captain, M. R. C.

U. S. Base Hospital No. 17, American Expeditionary Force, France.

NEWS OF THE TRAINING CAMPS

At Fort Riley

The second three months' period of this medical officers' training camp is nearly completed. The closing of the training camp at Fort Benjamin Harrison and the preparation for the next class of student officers at the camp have resulted in a number of changes in the staff of instructors. Lieut.-Col. H. F. Piper, M. C., comes here from Fort Benjamin Harrison as assistant commandant in general charge of instruction and in charge of student companies. Major H. M. Snyder, M. C., from Fort [illegible] is to take command of Hospital Train N[illegible] Hill, M. C., is to have charge of the professional examination of reserve officers. Major William H. Tefft, M. C., has been ordered here from Fort Douglas, Utah, to take command of Evacuation Hospital No. 7. Major Robert H. Duenner, M. C., has been ordered from Honolulu to Fort Riley to organize and command Hospital Train No. 25.

Meanwhile, preparations for new companies and for cold weather are going forward steadily. The barracks are being lined with tar paper and sheathing, and every effort is being made to have them warm and comfortable before the winter begins. Yet in spite of the lateness of the season, the beautiful Indian summer weather continues. Day after day of clear sunshine makes the outdoor work and especially the maneuvers a delight.

REGIMENTAL AND BRIGADE MANEUVERS

Following two weeks of training in equitation, each student company is given one week in regimental and brigade maneuvers and one week on a division problem. The first week, various student officers are detailed as regimental and battalion surgeons, and are given written orders directing them to proceed to certain locations designated on the map and to select suitable sites for regimental aid stations. Other student officers are detailed as commanding officers of ambulance companies, and are told to select a location for a dressing station under certain definite conditions. Other men are sent out with compasses and maps, and are told to find a regimental commander stationed at a point designated on the map and to report to him at a certain hour. In the brigade problem, brigade, regimental and battalion surgeons are appointed, ambulance companies and field hospitals are taken out and moved according to previously issued orders, and all the details of a regimental or brigade problem are worked out. But it is division maneuvers that are most fascinating. Here two companies of student officers are taken out, all the instructors are on staff duty, and all the field hospital and ambulance companies with their entire personnel and equipment are in the field, together with four or five hundred to impersonate wounded. The field of operations extends from Ogden on the east to Junction City on the west, and from North Gate to the Washington Street bridge, an area of about 30 square miles. The colonel himself is in command, and every one prepares for an all day ride.

Right after breakfast, the horses are brought up from the stables, each equipped with saddle bags. In one is the bag of oats that is to form the midday meal for the horse. In the other bag goes the lunch for the rider. The cooks have risen earlier than usual, and have made an incredible number of sandwiches. No thin and ladylike sandwiches are these, with wafer-like slices of bread and a delicate lettuce leaf between, but large, husky slices of camp bread with cheese, ham, roast beef or canned beef between them. The first day, some of the unwise arise from a hearty breakfast and scorn these mammoth hunks of nourishment, or take only a single package. But one day's riding is enough to impress on the shortsighted medical officer the amazing shrinkage that a sandwich can undergo. One that is too large to carry at 7 a. m., is so small by 12:30 that at least three are necessary to convince one that one has had any lunch. Thereafter preparedness is each man's motto. Not only does he fight with the cook to get two packages, but he even tries the time worn yarn about "the fellow in the cot next to mine didn't have time to get any and wants me to get his for him." Some, foiled by the watchful cook, wait a decent interval and then return for a second helping, with elaborate and carefully assumed innocence. But all get enough and the saddle bags are soon bulging, not only with packages of sandwiches, but also with oranges, apples, cakes of chocolate and boxes of cookies and crackers. Canteens, filled with water, tea or coffee, according to the taste of the owner, are swung to the saddle, stirrups are adjusted, girths are tightened and horses are looked over carefully, sometimes it must be admitted with some trepidation, for not all physicians are bold and dashing riders when they come here.

PREPARATION FOR BATTLE

Meanwhile, the field hospitals and ambulance companies, long lines of motor trucks or of mule drawn wagons, have come up and are waiting orders to move. The enlisted men go by in heavy marching order and halt in the road beyond. Then the headquarters automobile appears, orders are distributed to each commanding officer, and one by one the various commands move off to their stations. Only the headquarters staff is left, and finally it receives orders to report at Randolph Hill at 8:30. So off we go on a 4 mile ride. This is the Blue day, and we rode over the entire field yesterday, so every one knows where to go. A Blue army with its base at Manhattan is marching to attack a Red army that is defending Junction City. Randolph Hill, the highest point in the northeast quarter of the reservation, is Blue headquarters. From the top, one can view the entire field. It is a clear, sharp November morning. The sun is just getting up above the hills. The mist lies thick in the valleys, but the wind blows sharp and chill on the hill top. Sheepskin lined coats and heavy gloves feel good, though later on when the sun gets higher, even a khaki blouse will be too heavy.

The staff is gathering on the hill, each group as it comes up dismounting and giving the horses to the orderlies, who lead them to the rear. All gather about the colonel, who as division surgeon is in command of the entire sanitary force. Maps are spread out on the grass, and the Blue position traced out. Soon orderlies on horseback or on motorcycles begin to appear. The battle is on. Each commanding officer as he reaches his position reports to headquarters and receives further orders. Each detachment commander is given several sealed envelopes to be opened at 9, 10, 11 and 1:30. In them are orders for him to carry out, by which the progress of the battle is carried on. As each report reaches headquarters, the situation is discussed and members of the staff are asked to suggest a proper solution. As one commander after another reports heavy casualties, the director of ambulances or the director of field hospitals is called on to establish dressing stations, evacuate the wounded, or set up hospitals. An orderly is sent with a message to an ambulance company, awaiting orders several miles away, to advance by a certain road and take care of the wounded. The orderly disappears. Half an hour or an hour goes by without apparent result. Field glasses are brought out, and the road on which the ambulance train is to appear is closely watched. Finally some one shouts, "There they are," and far away, over the crest of the hill, appears the head of the column. Slowly the ten motor ambulances, the trucks and supply wagons, the automobiles and motorcycles wind across the ridge in a long procession and disappear in the valley below. Discussion is now heated. Did the commander expose himself and his train to the Red artillery fire on Morris Hill? If so, is he *hors de combat* or not? Finally, everybody agrees that "Ambulance Company 19 is all shot to hell," and that it is time for lunch anyway. So this interesting but convenient battle stops for lunch. Saddle bags are opened and everybody drops down on the dry, warm grass. Surely those sandwiches can't be as large as they were a few hours ago. Those who have secured a double supply congratulate themselves, while the less thrifty vow that tomorrow they will do likewise. Canteens are passed around, and cigarets, cigars and pipes are produced. By 1:30 the battle is resumed, and by 3 the Blue army is in full retreat, with a large number of wounded that must be cared for by the regimental surgeons, the dressing stations and the hospitals. How are they doing their work? At 3:30, the colonel folds up his map and draws on his gloves. "Mount up, gentlemen. We will ride the Blue battle line." And off we go. All the positions are carefully examined, the location of the regimental aid stations and dressing stations criticized, and the various problems involved discussed. From one position to another we go, sometimes by road or lane, more often across country, working back from point to point until we reach the Blue base, perhaps 8 or 10 miles behind the battle line. Here are gathered all the field hospitals, ambulance companies and sanitary troops. Tents are all pitched in perfect alinement; stoves are unpacked; even operating tables with instruments and basins are ready. Ambulances and motor trucks are parked in long rows. The men that are on field rations are cooking their supper, but all rise and stand at salute as the staff rides past. In front of each company are two flags, the Stars and Stripes and the Red Cross, twin emblems of Liberty and Mercy. We ride past the twenty-four big ward tents, the kitchens, the officers' tents and the long line of pup tents of the men, and finally in the glow of the early evening turn toward camp and supper, tired but feeling sure that of all the good things at Fort Riley, division maneuvers are the best.

DISEASE CONDITIONS AMONG TROOPS IN THE UNITED STATES

Extracts from Telegraphic Reports Received in the Office of the Surgeon-General for the Week Ending Nov. 16, 1917

1. Total strength of troops		1,065,418
Admission rate per 1,000 (disease only)	annual	1,412.7
Non-effective rate (all camps)		34.9
2. National Guard, strength (camps)		391,199
Admission rate per 1,000 all camps (disease only)	annual	1,697.3
Non-effective rate all camps (all causes)		42.6

Camps showing admission rate for disease higher than average: Camps Beauregard, Wheeler, Bowie, Kearney, Sevier and Cody.

Camps showing non-effective rate all causes higher than average: Camps Wheeler, Beauregard, Bowie, Sevier, Kearney, Shelby, Cody, and MacArthur.

3. National Army, strength (camps)		413,487
Admission rate per 1,000 all camps (disease only)		1,427
Non-effective rate all camps (all causes)		28.5

Camps showing admission rate for disease higher than average: Travis, Pike, Funston, Jackson, Lewis, Dix and Dodge.

Camps showing non-effective rate all causes higher than average: Camps Pike, Funston, Travis, Jackson, Lewis and Dodge.

4. Venereal Disease—		
Admission rate Regulars	annual	94.3
Admission rate National Guard (camps)	annual	74
Admission rate National Army (camps)	annual	95.3

Camps National Guard having rate above average: Camps Kearney, Beauregard, Wheeler, Sheridan, Logan and Doniphan.

Camps National Army having rate above average: Camps Jackson, Lee, Gordon, Sherman and Travis.

5. Number of cases of pneumonia		397
Highest number in any one camp	(Pike)	54
Number of cases of meningitis		48
Highest number in any one camp	(Funston)	13

NEWS OF THE CANTONMENTS

Thirty-First Division, Camp Wheeler, Macon, Ga.

BASE HOSPITAL NOTES

Major Richard Weil, chief of the medical service, died on Nov. 19, 1917, of pneumonia, contracted in line of duty. Undoubtedly conscientious work had much to do with his illness and untimely demise. His character, ability and personality greatly endeared him to all the officers, men and patients with whom he came in touch. Brief military honors were given the remains.

The Surgeon-General of the Army and staff visited the hospital, November 23 and 24. In addition to his personal staff, Dr. W. H. Welch of Johns Hopkins University accompanied him in an advisory capacity.

The porches are all screened with canvas and the patients seem happy and content and do not complain of the cold. The permanent stoves have been installed in practically all of the buildings. The officers' and isolation wards are now occupied, leaving the psychiatric ward only without patients.

Heavy clothing is coming at last, and it is hoped that pneumonia will decrease as a result of its arrival.

The hookworm treatment is being generally given, when chenopodium can be secured. This also will, it is hoped, reduce the amount of pneumonia.

SCARLET FEVER AND MENINGITIS

Scarlet fever has appeared in camp, there being in the hospital ten cases. Only two new cases of meningitis have developed since last week.

MEASLES

The epidemic of measles is drawing toward a close. Over 2,800 cases of measles have been treated in the base hospital. The high water mark was 1,201 cases in hospital. The greatest number received in one day was 175 cases. The number of deaths from bronchial pneumonia complication has amounted to a trifle more than 1 per cent. No middle ear or other complications have occurred, excepting bronchial pneumonia, and possibly tuberculosis.

PNEUMONIA

Pneumonia is the fatal disease of the camp and has not decreased with the decrease in measles. The total number of cases of lobar pneumonia has been 243. Of these practically 25 per cent. followed measles, and 75 per cent. was independent of measles. The percentage of deaths has been 11. Of eighty-eight cases, of which the type was determined by inoculating mice, seventeen were of Type I, six of Type II, five of Type III, and sixty of Type IV. A careful study of all pneumonia cases is being made and it is believed that much light will be thrown on the epidemiology of this disease. The theory that it is infectious and that cases are transmitted from other cases, either by direct or intermediate infection, is being insisted on by Colonel Duncan, the division surgeon.

VISITORS

Many distinguished visitors have been drawn to the camp recently; partly by reports of the epidemic of pneumonia.

Mr. W. J. Harris and Senator Hoke Smith were visitors on Wednesday. The daughters of Gen. Joe Wheeler were here on Monday.

On Friday, Surgeon-General Gorgas arrived from Washington, D. C., accompanied by Majors Victor Vaughan, T. C. Janeway, William H. Welch of Johns Hopkins University and Colonel Howard of the Surgeon-General's Office. The Surgeon-General and Majors Welch and Vaughan addressed all the medical officers at 2:30, and all the field officers of the division at 4 o'clock.

Colonel Fisher, medical inspector, was in the camp on Sunday and Monday, going on afterward to Jacksonville.

ONE HUNDRED AND SIXTH SANITARY TRAIN

The equipment of the train has been greatly augmented by the receipt during the past week of three complete equipments for ambulance companies and one equipment, complete, for field hospitals. The motor ambulances for Ambulance Company No. 123 have also arrived, have been assembled and are now in operation. The latter part of last week a consignment of ten Indian motorcycles with side-cars were delivered. This completes probably the motor equipment that will be delivered at this station. The Dodge cars for the motor companies and the directors have not and probably will not come.

The regular weekly social of the train was held in the recreation hall, Wednesday evening, and was largely attended. A most enjoyable evening was had to the strains of the orchestra of the Florida Field Hospital, which is now completed by the acquisition of a snare drum and base drum.

The process of eliminating from the train the large number of accumulated mascots, ranging from wolfhounds to Chihuahua dogs, goats, pet possums and rabbits, is progressing to a successful finish. The next few days will see the completion of this work.

NOTES

Coughs and "colds" are widespread in the camp and in this whole region. The dust, from the continued dry weather, seems to be a factor in the spreading of these coughs.

The Thirty-First Division has finally received a definite name, the Dixie Division, with the insignia ƆD, two D's, one reversed.

The work of the vice commission and of the local committee has finally begun to bear fruit in a cleaning up of Macon hotels, and in lessening the number of streetwalkers.

There is general comment on the poor class of men furnished by the draft. Many from the rural districts are miserable physical specimens, some with anemia from malaria, other from hookworm, others poorly developed, and all falling an easy prey to measles, pneumonia, or any other infectious disease. Although the weather is not at all bad, being rather fine, there is much sickness among the 10,000 drafted men; but very little among the 11,000, old guardsmen. While Camp Wheeler is called a National Guard camp, it is now almost one-half National Army, and will be three-fifths National Army when filled to war strength.

The Thirty-First Division has sent no patients to any hospital outside the camp. All patients, from the beginning, have been handled here, first in the field hospitals and later in the base hospital, which has cared for more than twice its rated capacity.

Thirty-Fifth Division, Camp Doniphan, Fort Sill, Okla.

Camp Doniphan and its base hospital were subjected to official inspection this week; Col. William R. Lewis looked after the sanitary conditions of the camp and Major M. Black, M. R. C., investigated the base hospital. Owing to the lateness of the authorization of necessary funds, the sewerage system has not yet been installed, and this will delay the completion of the hospital, it is estimated, for another month and one half to two months; in the meantime concrete cesspools are installed for some of the wards and the quarters for the staff.

The meeting of Wednesday night, November 14, was devoted to discussion of the venereal disease problem. Lieutenant C. A. Coleman, speaking from an extensive experience in private practice, outlined briefly what he believed to be essentials in the handling of the venereal disease problem of the Army. The paper was received with a great deal of interest, and was discussed by officers of the field as well as members of the staff of the base hospital.

Friday night, Capt. Lee H. Bailey of the British Army spoke on the use of the bayonet; though more military than medical, the paper nevertheless was listened to with a great deal of interest.

DISEASE INCIDENCE

The number of infectious diseases unfortunately is still on the increase, over forty pneumonia patients being treated at the hospital at this time. The past week also had two deaths from meningitis to record, one of which showed generalized infection due to the *Diplococcus intracellularis*. Though both of these cases were brought to treatment promptly, the serum treatment proved of no avail. Owing to the still incomplete state of the laboratory, it has not been possible to make satisfactory bacteriologic examination to determine the particular strain of the meningococcus; therefore it cannot be stated whether the death of these patients must be assigned to the presence of a foreign strain of the meningococcus or whether the serum used was defective.

Thirty-Eighth Division, Camp Shelby, Hattiesburg, Miss.

The medical organization of the Thirty-Eighth Division, which consists of National Guard troops from Indiana, Kentucky and West Virginia, is now almost complete.

The regimental infirmaries are being equipped with a modified Wolfe ward unit which gives a well equipped hospital of twenty beds for each regiment. Hotel ranges are supplied for the kitchens, and heating stoves are being installed.

On Monday and Thursday nights, meetings for all medical officers are held. Monday nights are devoted to medicomilitary subjects, and Thursday nights to purely professional papers with reports and presentation of clinical cases, of which there are an abundance in the base hospital.

BASE HOSPITAL

The base hospital is complete with the exception of the ceiling of the wards. On account of the present epidemic of measles, it is now crowded to its utmost, and the tentage of three field hospitals has been pitched to care for men with mild cases, thus relieving the congestion of the wards. The ward tents are floored, and have stoves and iron beds. In this camp, experience has proved that measles patients do fully as well under canvas as in buildings.

MEASLES

This camp, as well as many others, is suffering from an epidemic of measles. The disease, however, seems to be of a mild type, often running an afebrile course. There have been only two cases of pneumonia in 500 cases of measles, and no other complications. In an effort to control this epidemic, very strict orders have been issued regarding sanitation of tents, personal hygiene, and physical inspections. Although these orders are well carried out, they seem to have little or no effect on the development of new cases. Climatic conditions, dust and smoke, and the age of troops, together with the arrival of drafted men from other camps, no doubt have much to do with the continuation of the disease.

PNEUMONIA

There have been about sixty cases of pneumonia, principally of the lobar type and running a clear cut typical course. The death rate is low, only about 4 per cent., and the infection does not seem to be of a virulent type. The laboratory work of differentiating the various strains of pneumococci is now under way, and in a short time it will be possible to administer specific serum therapy in suitable cases.

MENINGITIS

During the month of October, six cases of meningitis developed in this command. Four were in one regiment and appeared within three days. The regiment was promptly moved to an isolation camp; rigid quarantine was instituted, and under the direction of a medical officer every man in the organization gargled his throat and douched his nose twice a day with Dobell's solution. As rapidly as possible, members of the companies in which the cases appeared were examined for carriers. When these were found, they were isolated from all others and given intensive treatment with dichloramin-T until negative cultures were secured. This prompt action evidently cut short an epidemic that was reaching alarming proportions. The cases were of moderate severity, with only one death.

PERSONAL

The office of the division surgeon is busy with routine work, special instructions, inspections, etc. Lieut.-Col. Robert M. Blanchard is the division surgeon; Major Larue D. Carter, division sanitary inspector, and Capt. Abraham C. L. Percefull, assistant to the division surgeon.

Colonel Blanchard, Majors Hibbitt and Grant of the sanitary train, and Majors Crawford and Lathrop of the base hospital staff recently returned from the meeting of the Southern Medical Society, held at Memphis, Tenn. It was hoped that Colonel Goodwin of the British Army would give this camp a visit; but it could not be arranged, much to the disappointment of all officers.

Social activities among the medical officers have been curtailed on account of the immense amount of work on hand. All are cheerful and happy, however, and not growing stale in their duties.

Eightieth Division, Camp Lee, Petersburgh, Va.

November 5, the regular course of instruction of medical officers and Medical Department enlisted men was put into effect. The course prescribes thirty-eight hours' work a week, and is being carried out by the sanitary train and regimental detachments. The work of the sanitary train is handicapped because no enlisted men have as yet been available for one ambulance company and three field hospitals.

A most interesting clinic was held at the base hospital on November 22, which was attended by the medical officers of the division and the base hospital. Major Ewing Day, M. R. C., described the functions of the semicircular canals and the various nerve paths leading from the canals to the brain. Major Day also demonstrated the Bárány test on a normal individual and also on a man who had become deaf as a result of cranial injury. Major William L. Peple, M. R. C., gave an illuminating talk on appendicitis, stating that twenty cases had been admitted to the base hospital since its opening and all had been operated on and were doing well. Capt. Joseph B. Sayles, M. R. C., showed an interesting case of pellagra and one of favus.

A regular meeting of the medical officers attached to the division and base hospital is being held weekly on Wednesday afternoons at which administrative affairs are discussed. Thursday evenings a clinical meeting is held at the base hospital.

At the clinical meeting, November 15, Major Ross Moore, M. R. C., chief of the neurologic section of the base hospital, demonstrated a series of cases showing types of mental cases and diseases in the Army. Two neuropsychopaths, one hypochondriac, two dementia praecox patients and two with paranoid personality were shown. The officers were much interested in the clinic, and there was general discussion as to whether any of the men demonstrated should remain in the Army.

NEUROLOGIC EXAMINATIONS IN THE DIVISION

During the last ten days the routine neurologic examination of enlisted men in this division has been begun in earnest. Capt. J. M. W. Scott of Schenectady, N. Y., has been acting as neurologist to the base hospital ever since its opening, two months ago. About November 1, Lieut. Bennett A. Burks of Alabama, Lieut. Dudley C. Kalloch of Ossining, N. Y., and Major Ross Moore of Los Angeles arrived for the purpose of making this routine examination.

Approximately 20,000 out of the 33,003 troops in camp have already been examined by the psychologists. The final discards from this examination, the mental defectives of such low degree as to be considered unfit for duty by the psychologists, are being studied by Major Moore and his assistants to determine their final disposition.

During the early weeks of psychologic testing, the mental age of 10 years was gradually settled on by Captain Scott and the psychologists as being the lowest average level for Army service. This conclusion was based on studies of companies that were composed to a large extent of American born men of American born parents. Studies made during the last ten days of some companies from western Pennsylvania and West Virginia, composed in large proportion of foreign born men, mostly illiterates, are showing that a mental age of 10 years is too high. Many men have been accepted for the Army who can neither read nor speak English, but who are expert workmen in steel mills, etc., and whose mental age lies between 8 and 10 years. The general conclusion at present, therefore, is that foreign born illiterates of a mental age of 8 years and upward will make good Army material, while 10 years and upward is the low limit for American born illiterates. The differentiation is a very real one, and is graphic evidence of how men differ in their ability to react to surroundings. The many American born illiterates of these examinations have had opportunities for intellectual betterment but have not profited by them or have even retrograded, while many of these foreign born illiterates have had no such advantages but are eager to secure what they can now. In these large group tests the proportion of illiterates included is great enough to make a difference of two years in the age of acceptance between American and foreign born illiterates. This phase of the investigation is still young. Other conclusions may be reached after further study. Another and a larger psychiatric and neurologic study now in process of accomplishment is the study of the enlisted men with a view to the elimination of the unfit. The latter are the pathologic, neuropaths and psychopaths, and the insane. The feebleminded are being inexorably detected by the psychologists, and their final disposition is easily accomplished. The detection of the psychopaths and neuropaths is quite another matter. The plan in use at the present is as follows: Work is done by regiments in regimental infirmaries. The regimental medical officers are asked to hand in the names of men who have been noted as acting queerly in some way, or to be unable to fit themselves into the Army life well enough to get along—men who seem unable to learn the drill, etc.—and all men suspected of malingering. These men are studied individually by the neurologists, the evidence of their company commanders is taken, they are put through drill and other tests, and are often sent to the base hospital neurologic wards for observation. In other cases they are returned to the ranks for two weeks for further training. It is thought that this procedure will ultimately eliminate a large proportion of the neurologically unfit.

HEALTH OF THE DIVISION

The general health of the division remains good although an outbreak of mumps and measles, limited to two regiments has increased the sick rate. There are sixty-four cases of measles and one hundred and thirty-one cases of mumps. There have been twenty cases of pneumonia and only one death, and eight cases of cerebrospinal meningitis with but one death.

VENEREAL DISEASES

Effort is being made to secure a report of every new case of venereal disease whether the man is in hospital, quarters or doing duty. In order to study carefully the work of each infirmary, a weekly report on prophylaxis and venereal disease is rendered by each organization surgeon. The prophylactic treatments given during the week are grouped into those given within an hour, one to two hours, two to four hours, four to eight hours and over eight hours. The number of cases of gonorrhea, chancroid or syphilis which occur in spite of prophylaxis are reported and grouped according to the time the prophylactic treatment was given. Cases that were undoubtedly infected prior to enlistment are classified separately as are also cases that have developed in men who fail to take prophylactic treatment. Prophylaxis stations are maintained in Hopewell, Va., a city of 15,000 people, 6 miles away and in Petersburg, four miles away, a city of 30,000. By means of the reports it will be possible to learn the proportion of cases occurring in the various commands before and after enlistment, the efficacy of prophylaxis early and late and the extent of immorality, and finally the definite number of cases of syphilis, gonorrhea and chancroid.

Eighty-Fourth Division, Camp Zachary Taylor, Louisville, Ky.

ATHLETIC TRAINING

Compulsory athletic training has been added to the schedule of daily life at Camp Zachary Taylor. Heretofore, the soldiers have spent eight hours a day at drill; now one hour a day at athletics will be substituted for an hour of drill. From 10:30 to 11:30 each day, compulsory athletics on a scientific and systematic basis will be indulged in. There will be physical drill or calisthenics, boxing and wrestling, football, blocking, charging and tackling, obstacle and relay racing, basketball, volley ball, baseball and soccer football. An athletic officer has been appointed in each regiment, separate battalion and independent unit, who are charged with supervision and direction of the physical training, with a Louisville man, Capt. George R. Ewald, as division athletic officer. Eight men are in the hospital because of injuries received in these exercises, two with fractures of the clavicle.

CONSCIENTIOUS OBJECTORS

Sixty members of the Mennonite faith from Illinois sprang a surprise on the division paymaster when they refused to accept their pay. They are conscientious objectors, and are called absolutists, as they object to serving in the Army in any capacity. The only work they are performing is keeping their quarters clean.

MEASLES

Heavy punishment is being meted out by the summary court martial in the Three Hundred and Thirty-Sixth Infantry to men who break the quarantine for measles and go into the city without leave. Three men recently tried in Company D were sentenced to ninety days in the guard house and three months' loss of pay. The epidemic as far as new cases are concerned is about over. One death has occurred from a complicating bronchopneumonia. Each organization has received orders to be prepared to send its men to the base hospital, on request of the division surgeon, for the psychologic examination. Every man in camp will eventually be put through these tests.

AMBULANCE COMPANIES

Ambulance equipment for the Three Hundred and Ninth Sanitary Train has arrived, and this organization will perform the ambulance service for the entire camp. Four companies of the sanitary train are known as ambulance companies; two more motor drawn units, and the other two derive their power from the famous Army mule. Ambulances will call at 9 o'clock each morning and 3 o'clock each afternoon at all regimental infirmaries and transfer patients to the base hospital. Two ambulances are kept on duty at the base hospital day and night.

First Lieut. Lynn T. Hall of Ambulance Company No. 355 has been designated as attending surgeon of the Infantry School of Arms. He will maintain a dressing station near the school, and will have an ambulance ready at all times.

NURSING SERVICE

More Red Cross nurses have reported to Major J. A. Worthington, the nursing staff now numbering thirty-four. A meeting was held on the 19th at the Children's Free Hospital for the purpose of stimulating interest in Red Cross nursing and recruiting for the base hospital at Camp Zachary Taylor. A reception to the Army nurses on duty was held after the meeting. A number of the nurses assigned to Base Hospital No. 40, Lexington, Ky., have asked for transfer to the base hospital at Camp Zachary Taylor pending foreign orders.

REPORTS OF MEDICAL OFFICERS

Several medical officers from the base hospital attended the meeting of the Medico-Chirurgical Society, November 16. Major Hamburger made a brief report of the epidemic of measles that has been so prevalent in two regiments, and now has begun to spread among those attached to the hospital, one nurse, one medical officer in the eye section, and several hospital attendants being affected. The rashes have been almost uniformly severe, a large percentage being hemorrhagic. There have been a number of complicating bronchopneumonias, and the marked early cyanosis in these cases has been an outstanding feature. In the fatal cases the necropsy findings in the lung have been uniformly a most diffuse riddling of the lung with patches of bronchopneumonia and a great amount of exudate everywhere.

The seven meningitis patients are doing well under the serum treatment; four are convalescent. The lobar pneumonia patients have progressed well, with a very small percentage of deaths.

Lieutenant Alexander, who has had long training in the laboratory side of pneumonia in Boston, New York and Baltimore, reported that 65 per cent. of the lobar pneumonias have been found due to Types I and II, and that these organisms are not found in normal mouths. The bronchopneumonias are due to a typical Type II, and Types III and IV, and these types are found normally in healthy mouths. On this theory more consistent and regular oral hygiene and antisepsis will be used in the measles cases particularly. A good deal of polyvalent serum has been used, and a shipment of Type I serum has just been received. The cases at Rockefeller Hospital under the specific serum treatment reduced mortality from 30 per cent. to 5. The polyvalent serum is used before the type of organism is known. It is purposed to standardize the various types of serums received from the manufacturers. In the tests some of the serums have been found useless in vitro. It is hoped that all can be standardized.

Major Wilder and Captain Littig of the ophthalmologic staff at the hospital occupied the program of the regular meeting of the ophthalmologic society, on the 15th.

BASE HOSPITAL

The base hospital, now nearly completed in every detail, occupies 85 acres and sixty-seven buildings, with 1,000 beds. Sixty-five physicians, 288 enlisted men and thirty nurses care for the 560 patients now in the hospital.

Eighty-Eighth Division, Camp Dodge, Des Moines, Iowa

An intensive course of training for all medical officers has been outlined by Lieutenant-Colonel Shook, the division surgeon, pursuant to an order from the Surgeon-General. Excellent lectures have already been given by Major Miller on "Foreign Protein Therapy"; Major Ruth on "Treatment of Fractures of Head and Neck of Femur"; Captain Baehr on "War Psychiatry"; Captain Glomset on "Carriers," with special reference to typhoid, diphtheria, epidemic meningitis and pneumonia, and by Major Todd on "Practical Hints to Military Medical Officers on the More Common Diseases and Treatment of the Eye, Ear, Nose and Throat."

The Camp Dodge Medical Society, composed of all the medical officers of this cantonment, has been formed with Major Todd as president. Meetings are being held weekly. Interesting and instructive papers have been given by Contract Surgeon Feil and Captain Franing.

Major John Ridlon was in camp about ten days ago, and gave a series of lectures and demonstrations to medical and line officers.

NEWS NOTES

Col. Charles Dircle of the Medical Department of the French Army and Col. T. H. Goodwin of the British Medical Service visited and inspected this cantonment some time ago. They report that the camp and type of work being done is excellent. Each officer spoke before the meeting of the Polk County Medical Society on that date, and gave some interesting and vivid descriptions of modern warfare.

Major Alexander Cooper of Fort Oglethorpe, Ga., has been assigned as commanding officer of the base hospital.

Major E. O. Craft has been assigned as commanding officer of the base hospital at Presidio, Calif. He was highly commended by the commanding general for his excellent work of organizing and commanding the base hospital at this camp.

Capt. E. C. G. Franing of Galesburg, Ill., has been given detached service at Chicago, to attend the special course on fractures given there.

Capt. L. L. Henniger of Council Bluffs, Iowa, has been transferred to Fort Porter, N. Y.

Lieut. John Voss and M. C. Frazier have been given detached service at Chicago, to attend a special course on oral surgery.

BASE HOSPITAL

The base hospital moved into permanent quarters, October 25 and 26. The new hospital is situated at the northwestern end of the camp, close to the village of Herrold. It is composed of thirty-two buildings, built about a central quadrangle about 100 yards wide and 150 yards long. These buildings are all connected by closed corridors.

Eighty-Ninth Division, Camp Funston, Fort Riley, Kan.

INCLEMENT WEATHER

The weather at this camp was a subject of great disparagement during the latter part of October. It was typical winter weather, accompanied by snow storms, and, as the heating plants were not installed, one often had to go to bed to keep warm. At present we are having beautiful, warm winter days and clear nights, and it is unnecessary to heat the barracks, excepting for a short time each morning.

INSPECTION

Col. W. P. Chamberlain, M. C., and Col. George E. Bushnell, M. C., of the War Department, have just completed a tour of inspection of the camp, and they have expressed themselves favorably regarding the condition of the cantonment. They could hardly believe that the number of new cases of venereal disease contracted by men after coming to this camp was so low. Since the camp was started, there have been but five, and prophylactic treatments have been likewise sparingly called for, although every man in the division has been properly instructed on the subject.

QUARANTINE

With regard to the prevention of disease in this camp, a quarantine has been established between the Ninety-Second and the Eighty-Ninth divisions, and the men from the two do not intermingle, conducting all drills and duties separately. As another step, all of the roads, dirt or macadamized, have been well oiled and rendered dustless.

MENINGITIS

By taking frequent and systematic cultures, a number of meningococcus carriers among the new troops have been apprehended and isolated, and as a result few new cases of meningitis are expected.

Ninety-First Division, Camp Lewis, American Lake, Wash.

The cantonment at Camp Lewis is on a prairie 16 miles southwest of Tacoma; it is 2¾ miles long by 1 mile wide. The soil is composed of much small rock and gravel, and the drainage is excellent. Construction was started, June 20, 1917, and completed, according to the original plan, September 15. There are 1,600 buildings all told on the ground, 35 miles of water pipe, and 35 miles of sewer line. Lieut.-Col. Peter C. Field, M. C., is division surgeon, Lieut.-Col. Lloyd L. Smith, M. C., division sanitary inspector, and Major Eugene G. Northington, M. C., commanding officer, of the base hospital. The remaining medical officers belong to the Medical Reserve Corps, and hail from all parts of the West and particularly from the Northwest. There are 166 medical officers, 20 contract surgeons, 38 dental officers and 15 veterinarians.

The sanitary condition of this camp is excellent. Very few cases of acute contagious diseases have appeared. The prevailing diseases are those of the upper respiratory tract: bronchitis, tonsillitis and pharyngitis.

The following officers are in charge of the different services of the base hospital: Major Eugene G. Northington, M. C., commanding officer; Major Herbert M. Greene, M. R. C., adjutant; Major Calvin S. White, M. R. C., chief of the medical service; Major John J. Kyle, M. R. C., chief of the ophthalmic division; Capt. Ernest L. Bickford, M. R. C., chief of the laboratory service; Capt. Edward A. Rich, M. R. C., chief of the orthopedic service; First Lieut. Horace J. Whitacre, chief of the surgical service, and Capt. Rawlins Cadwallader, M. R. C., post exchange and mess.

The operating room and roentgen-ray room are completed in every detail and are running in smooth order. The hospital is fully equipped throughout with steam heat and electric lights. There are now attached to the hospital, 40 medical officers, 30 female nurses and 240 hospital corps men. The base hospital and sanitary train occupy about 40 acres.

Nearly all cases of venereal diseases were contracted before the men arrived at camp. Only two new cases have been reported. Practically the entire command is vaccinated against smallpox; typhoid and paratyphoid prophylaxis has been given. All new men are marched from the train to the receiving tent, where they are carefully examined for contagious and venereal diseases.

ORDERS TO OFFICERS OF THE MEDICAL CORPS

To Camp Beauregard, for duty, Lieut. ERNEST E. ALLGEYER, New Orleans.

To Camp Sheridan, base hospital, from Plattsburg Barracks, Capt. GEORGE W. JEAN.

To Camp Mills, as inspector instructor of sanitary personnel and on completion to return to his proper station, Major CONDON C. McCORMACK.

Col. GEORGE E. BUSHNELL, to the following named camps to inspect the work of tuberculosis examiners and on completion to his proper station, *Camp Beauregard, Camp Pike, Camp Funston, Denver, Colo., Camp Dodge, Camp Grant.*

Major EDGAR KING, to the following named places for duty in connection with the development of special hospitals, and on completion to his proper station, *Long Beach, Asbury Park.*

Major EDGAR D. CRAFT, *to San Francisco,* Letterman General Hospital for duty, from Camp Dodge.

Lieut.-Col. CHARLES F. CRAIG, to be relieved from duty at the dept. laboratory, Fort Leavenworth, Kan., and to the following camps to inspect the Public Health Laboratory work, and on completion to proper station: *Camp Dodge, Camp Grant, Camp Custer, Camp Sherman, Camp Taylor, Camp Funston.*

Col. BASIL H. DUTCHER, be relieved from duty in the Panama Canal Dept. and *to Washington, D. C.,* to report in person to the Surgeon-General for duty.

Col. HENRY C. FISHER, to the following named places to make sanitary inspections, and on completion to his proper station, *Camp Wheeler, Camp Beauregard, Camp Shelby, Camp Jackson, Camp Sevier.*

Col. DAVID BAKER, relieved from duty at El Paso, Tex., and *to Camp Sheridan* for duty in command of the base hospital.

Lieut. GEORGE W. BELLER, relieved at Fort Casey, Washington, and *to Seattle,* for duty as medical member of examining board and recruiting officer.

Lieut.-Col. WILL L. PYLES, relieved at Fort Niagara, N. Y., and to the following named places to inspect buildings and sites under consideration for use as hospitals, and on completion to his proper station, *Rochester, N. Y., Dansville, N. Y., Avon, N. Y.*

Major LEARTUS J. OWEN, relieved at Letterman General Hospital, San Francisco, Calif., and assigned *to station in Washington, D. C.*

Lieut.-Col. WILLIAM R. MONCRIEF, *to New York* for duty, and on completion to his proper station.

Major WILLIAM E. HALL, relieved in the Panama Canal Dept. *to Governors Island, N. Y.,* for duty.

Lieut. EDWARD A. COATES, Jr., relieved at Fort Des Moines, Ia., and *to Fort Riley* for duty.

Lieut.-Col. JOHN R. BOSLEY, relieved at Fort Ontario, N. Y., and *to Hot Springs, Ark.,* for observation and treatment.

Major WILLIAM H. TEFFT, *to president of examining board, Fort Riley,* for examination for promotion, from Fort Riley.

Major WILLIAM L. HART, *to Baltimore, Md.,* to inspect the Maryland State Hospital Train, and on completion to return to his proper station.

ORDERS TO OFFICERS OF THE MEDICAL RESERVE CORPS

Alabama

To Annapolis Junction, Md., from Camp Wheeler, Lieut. WILLIAM M. PIERCE, Tuscumbia.

To Camp Beauregard, as a member of board for special examination of command for tuberculosis, Lieut. FLOYD L. ABERNETHY, Flomaton.

To Fort Logan H. Roots, Ark., for duty, from Fort Oglethorpe, Lieut. CLAUDE C. McLEAN, Birmingham.

To Fort Oglethorpe, for duty, from Camp McClellan, Lieut. WILLIAM W. BURNS, Selma.

To Fort Riley, Kan., for instruction, Lieut. DUKE C. BRADFORD, Birmingham.

To New York City, Neurological Institute, for intensive training in brain surgery, from Camp Greenleaf, Lieut. FRANCIS M. INGE, Mobile.

To Springfield, Mass., for duty, from Fort Benjamin Harrison, Lieut. HENRY BOXER, Birmingham.

Arkansas

To Camp Dodge, for examination of command for tuberculosis, from Fort Benjamin Harrison, Capt. PERRY C. WILLIAMS, Texarkana.

To Camp Joseph E. Johnston, for duty, from Fort Oglethorpe, Lieut. ERTON E. POYNOR, Green Forest.

To Fort Oglethorpe, for duty with Evacuation Hospital, No. 5, Lieut. MAHLON D. OGDEN, Little Rock.

To Fort Riley, Kan., for instruction, Lieut. CAP J. CARTER, Sherrill.

To Washington, D. C., Government Hospital for the Insane, for special training, from Surgeon-General's office, Capt. EDWIN P. BLEDSOE, Little Rock.

To his home and honorably discharged on account of being physically disqualified for active service from Camp Greenleaf, Lieut. TRUE S. BURGESS, Russellville.

California

To Camp Doniphan, base hospital, from Jefferson Barracks, Capt. CARO W. LIPMAN, San Francisco.

To Camp Fremont, Palo Alto, Calif., Base Hospital No. 47, Capt. HAROLD SIDEBOTHAM, Santa Barbara.

To Camp Lewis, Tacoma, Wash., for duty, Lieut. FREDERICK A. COLLER, Los Angeles.

To San Francisco, Calif., for duty examining troops for tuberculosis, from Camp Kearney, Capts. JOSEPH A. PARKE, San Diego; WILLIAM R. P. CLARK, JAMES L. WHITNEY, San Francisco.

To New York City, Neurological Institute, for intensive training in brain surgery, from Camp Lewis, American Lake, Wash., Major ALANSON WEEKS, San Francisco.

Canal Zone

To Army Medical School, Washington, D. C., for instruction, Lieut. WILLIAM B. FOSTER, Jr., Ancon.

Colorado

To Boston, Mass., for duty, from Camp Lewis, American Lake, Wash., Major WALTER A. JAYNE, Denver.

To Camp Sherman, as member of board for special examination of command for tuberculosis, from Fort Benjamin Harrison, Lieut. ORION A. GRANTHAM, Johnstown.

To his home and the inactive list of the Medical Reserve Corps, Lieut. JAMES R. ARNEILL, Denver.

Connecticut

To Camp Sherman, as member of board for special examination of command for tuberculosis, from Fort Benjamin Harrison, Lieut. EDWIN S. BENNETT, New Canaan.

To Newport News, for duty, Lieut. LLOYD L. NAURER, New Haven.

To New York City, Neurological Institute, for intensive training in brain surgery, from Camp Upton, Major WILLIAM F. VERDI, New Haven.

District of Columbia

To Camp Jackson, base hospital, Lieut. HENRY MAYES, Washington.

To Fort Myer, Va., for duty with the Twelfth Field Artillery, Major CHARLES L. G. ANDERSON, Washington.

To Fort Riley, for duty with Evacuation Hospital No. 7, from Fort Oglethorpe, Capt. THOMAS W. O'REILLY, Washington.

Florida

To Camp Hancock, base hospital, from Camp Greenleaf, Lieut. ROBERT E. BALDWIN, Tampa.

To Fort Oglethorpe, for duty, from Camp Wheeler, Lieut. HENDLY F. HORNE, Jacksonville.

To Fort Riley, for duty, from Fort Des Moines, Capt. MORETON H. AXLINE, St. Petersburg; Lieut. CHARLES L. KENNON, Jacksonville.

To Tenafly, N. J., base hospital, from Camp Wheeler, Lieut. WILLIAM H. G. MacKAY, Jacksonville.

To Washington, D. C., American University, for duty, from Camp Greenleaf, Capt. FREDERICK C. MOOR, Tallahassee.

To the inactive list on account of being physically disqualified for active service, from Fort Oglethorpe, Lieut. HEBER P. NEWMAN, Bartam.

Georgia

To Atlanta, Ga., dept. laboratory, from Rockefeller Institute, Lieut. ALLEN H. BUNCE, Atlanta.

To Camp Gordon, base hospital, from Camp Wheeler, Lieut. FRED B. RAWLINGS, Sandersville.

To Fort Oglethorpe, for duty, from Walter Reed General Hospital, Capt. THOMAS C. DAVISON, Atlanta; from Camp Wheeler, Lieut. JOHN TERRELL, Jr., Canon; from Chickamauga Park, Lieut. EGBERT M. TOWNSEND, Tilton.

To Fort Porter, N. Y., United States Army General Hospital No. 4, for duty with Hospital Unit "A", Lieut. WALTER E. HOLMES, Jr., Macon.

To New York City, Post-Graduate Medical School and Hospital for instruction in urology and dermatology, Capt. JOHN M. SIGMAN, Macon.

To Rockefeller Institute, for instruction, and on completion of this course to return to his proper station, from Fort Oglethorpe, Capt. GEORGE A. TRAYLOR, Augusta, and on completion of this course to Atlanta, Ga.; dept. laboratory, Lieut. ALLEN H. BUNCE, Atlanta.

To be honorably discharged on account of being physically disqualified for active service, from Fort Des Moines, Lieut. GEORGE W. P. JOHNSON, Savannah.

Idaho

To Camp Funston, for duty, from Fort Riley, Lieut. ROBERT S. KNEESHAW, St. Maries.

To Fort Omaha, Neb., United States Army Balloon School, for duty, Capt. FRANCIS H. POOLE, Pocatello.

Illinois

To Army Medical School, Washington, for duty, Lieut. CARL W. CLARK, Chicago.

To Boston, Mass., for instruction in orthopedic surgery, from Camp Grant, Lieut. CLARENCE A. JACOBSON, Chicago, from Fort Oglethorpe, Lieut. TORRANCE REED, Chicago.

To Camp American University, for duty, from Fort Benjamin Harrison, Lieut. FREDERICK E. ROBERG, Joliet.

To Camp Bowie, base hospital, from Rockefeller Institute, Capt. FREDERICK LUDWIG, Great Lakes.

To Camp Dodge, for duty, from Fort Riley, Lieuts. CHARLES A. CIBELIUS, FREDERICK G. TEST, Chicago; for examination of command for tuberculosis, from Fort Benjamin Harrison, Lieut. TIMOTHY C. WEBER, West Salem.

To Camp Doniphan, base hospital, from Fort Riley, Lieut. JOHN M. KRASA, Chicago.

To Camp Funston, for duty, from Fort Riley, Capt. WILFRED H. GARDNER, Bloomington; for examination of command for tuberculosis, from Fort Benjamin Harrison, Capt. CHARLES H. POWELL, Old Ripley; Lieut. CLARENCE W. CHAPIN, Weldon.

To Camp Grant, base hospital, from Fort Benjamin Harrison, Lieuts. BENJAMIN F. ZOBRIST, Camargo; LORAN E. ORR, Petersburg; as member of board for examination of command for tuberculosis, from Camp Bowie, Lieut. ROBERT S. BERGHOFF, Chicago.

To Camp Greene, for duty, from Fort Benjamin Harrison, Lieuts. HERBERT G. HEMPLER, Creal Springs; RALPH E. POTTER, Loraine; for duty from Fort Morgan, Lieut. FREDERICK T. RICE, Chicago.

To Camp Lee, for duty, from Fort Oglethorpe, Lieuts. HULITT J. WYCKOFF, Chicago; from Philadelphia General Hospital, WILSON K. DYER, Kankakee.

To Camp Logan, base hospital, from Fort Benjamin Harrison, Lieut. ARTHUR B. CONNOR, Wheaton.

To Camp McArthur, base hospital, Lieut. EUGENE Y. YOUNG, Mansfield.

To Camp McClellan, for temporary duty, from Evans Dental Institute, Philadelphia, Pa., Lieut. WILLIAM H. MALEY, Galesburg.

To Camp Pike, Little Rock, base hospital, from Fort Benjamin Harrison, Lieut. ROBERT B. MILLER, Rock Island.

To Camp Sherman, for temporary duty from Evans Dental Institute, Philadelphia, Pa., Lieut. RALPH E. KLECKNER, Mattoon.

To Camp Taylor, for examination of command for tuberculosis, from Fort Benjamin Harrison, Lieut. WILLIAM S. NEEDHAM, Hanna City.

To Camp Upton, base hospital, from Fort Benjamin Harrison, Lieut. CLYDE F. BACCUS, Woodstock.

To Chicago, Ill., for instruction and on completion to return to Fort Sheridan for duty, from Fort Sheridan, Lieut. WILLIAM A. CLARK, Chicago.

To Fort Oglethorpe, for duty, from Camp Dix, Lieut. EVERETT P. COLEMAN, Canton.

To Fort Riley, for instruction, Lieut. ROBERT S. WISHARD, Wheeler; for duty, from Fort Des Moines, Lieut. LEE C. GATEWOOD, Chicago; for duty with Evacuation Hospital No. 7, from Plattsburg Barracks, Lieut. JAMES H. VETTER, Chicago; from Washington University, St. Louis, Mo., Lieut. EDWIN W. HIRSCH, Chicago.

To New York City, Neurological Institute, for intensive training in brain surgery, from Camp Pike, Capt. WILLIAM FULLER, Chicago.

To Portland, Ore., for instructions and assignment to squadrons now being organized, from Fort Worth, Tex., Lieut. JOEL E. TOOTHAKER, Ladd.

To Richmond, Va., for duty, from Fort Benjamin Harrison, Lieut. RALPH R. TRUEBLOOD, Lawrenceville.

To Rochester, Minn., for instruction and on completion of course to Camp Beauregard, from Fort Benjamin Harrison, Lieut. THOMAS B. KELLY, Du Quoin; on completion to Camp McClellan, Lieut. WILLIAM L. MENG, Belleville; on completion to Camp Sherman, Lieut. RAYMOND M. Kelly, Chicago; on completion to Fort Sheridan, Lieut. LUTHER B. HIGHSMITH, Flat Rock.

To Rockefeller Institute, for instruction and on completion of course to Roosevelt Hospital, for a further course of instruction, and on completion of course to Fort Logan for temporary duty, from Fort Benjamin Harrison, Capt. VERNON C. DAVID, Chicago.

To his home and honorably discharged on account of being physically disqualified for active service, Lieut. EDWARD E. EDMONDSON, Mt. Vernon; from Fort Benjamin Harrison, Lieut. EARL R. COCHRAN, Rockton.

Indiana

To Camp Dodge, for duty, from Fort Benjamin Harrison, Capt. HARRY B. WILLIAMS, Mace.

To Camp Grant, base hospital, from Fort Benjamin Harrison, Lieut. WARREN W. HEWINS, Evansville.

To Camp Lee, for duty, from Philadelphia, Pa., Capt. ALFRED P. ROOPE, Columbus.

To Camp Meade, for duty, from Fort Benjamin Harrison, Lieut. JAMES O. RHEA, Linden.

To Camp Shelby, for duty, Lieut. IVAN E. BRENNER, Winchester.

To Camp Sheridan, for duty, from Camp Pike, Capt. Allen Hamilton, Fort Wayne.

To Camp Sheridan, as member of board for examination of command for tuberculosis, from Fort Benjamin Harrison, Lieut. AMZI W. HON, Indianapolis.

To Camp Travis, for duty, Lieut. GEORGE L. MARSHALL, Bourbon.

To Camp Wheeler, for duty, from Fort Benjamin Harrison, Capt. JAMES W. DUCKWORTH, Indianapolis; Lieut. JOHN W. PAHMEIER, Indian Springs.

To Fort Oglethorpe, for duty, from Camp American University, Lieuts. LLOYD A. ELLIOT, Elkhart; from Fort McClellan, Lieut. ELMER C. SINGER, Fort Wayne.

To Fort Omaha, Neb., for duty with balloon squadrons for overseas, from Fort Benjamin Harrison, Lieuts. FREDERICK L. DARROW, East Haven; CHARLES R. ELFERS, New Augusta.

To Honolulu, Hawaii, for duty, from Fort Benjamin Harrison, Lieuts. JAMES H. JOHNSON, Connersville; EUPY K. SCHURTZ, Waterloo.

To New York City, Neurological Institute, for intensive training in brain surgery, Capt. THOMAS M. JONES, Anderson; to Post Graduate Hospital for instruction in urology and dermatology, Lieut. ASHTON M. BALDWIN, Marion.

To Portland, Ore., for instructions and assignment to squadrons now being organized from Fort Worth, Tex., Lieut. CARLOS C. ROZELLE, LeGrange.

To Rochester, Minn., for instruction and on completion of course, to Camp Sevier, Lieut. LLOYD H. SIMMONS, Millersburg.

To Tenafly, N. J., for duty in Ice Plant Company, No. 301, from Fort Benjamin Harrison, Lieut. CHARLES W. ASHLEY, Bicknell.

Honorably discharged on account of being physically disqualified for active service, Major ORANGE G. PFAFF, Indianapolis.

Honorably discharged from Camp Custer, Lieut. GARLAND D. SCOTT, Sullivan.

Iowa

To Boston, Mass., for orthopedic instruction, from Camp Greenleaf, Lieut. GARNETT S. FELT, New Providence; from Fort Snelling, Lieut. EDWARD S. PARKER, Idagrove.

To Camp Custer, base hospital, from Fort Benjamin Harrison, Lieut. WILLIAM H. BETTS, Madrid.

To Camp Dodge, Des Moines, Ia., for duty, from Fort Des Moines, Capt. HANS HANSEN, Logan.

To Camp Sherman, Chillicothe, Ohio, Eighty-Third Division as member of board for examination of command for tuberculosis, from Camp Greenleaf, Lieut. HARRY C. NICHOLS, Carson.

To Camp Upton, Yaphank, L. I., N. Y., for temporary duty, base hospital, Lieut. HAROLD L. BRERETON, Emmetsburg.

To Fort Logan H. Roots, Ark., for duty, from Fort Benjamin Harrison, Lieut. ORSON A. KELLOGG, Dows.

To Fort Riley, Kan., for instruction, from Camp Dodge, Capt. JAMES J. DALY, Decorah.

To New York City, from Philadelphia, for duty in connection with the physical examining unit, and on completion to proper station, Major SUGEN R. LEWIS, Dubuque.

To New York City, Neurological Institute, for intensive training in brain surgery, Capt. HENRY A. GRAY, Keokuk; from Fort Riley, Lieut. FREDERICK W. SALLANDER, Fort Madison; to report to the chief surgeon, aviation section, for temporary duty, and on completion to Garden City, L. I., from Fort Benjamin Harrison, Lieut. VICTOR E. BOLLINGER, Mt. Pleasant.

To his home and the inactive list on account of being physically disqualified for active service, from Camp Dodge, Lieut. ROBERT C. MOLISON, Marshalltown.

Kansas

To Camp Devens, Ayer, Mass., for temporary duty, from Evans Dental Institute, Philadelphia, Lieut. IVAN R. BURKET, Winfield.

To Camp Jackson, Eighty-First Division, Columbia, S. C., for duty, from Fort Riley, Kan., Major JOHN E. HEWITT, Wakefield.

To Camp Mills, Garden City, L. I., N. Y., from Gas Defense School, Fort Sill, Okla., Capt. GEORGE W. LEE, Yates Center.

To Fort Riley, Kan., base hospital, for duty, from Medical Officers Training Camp, Fort Riley, Lieut. CHARLES V. HAGGMAN, Scandia.

To New York City, Cornell Medical College, for instruction in military roentgenology, Lieut. GEORGE E. KNAPPENBERGER, Mankato.

To Rock Island, for duty, from Fort Riley, Lieut. RALPH C. HENDERSON, Erie.

To his home and the inactive list on account of being physically disqualified for active service, Lieut. JAMES B. DONNELL, Kinsley.

Kentucky

To Camp Lee, Petersburg, Va., base hospital, from Camp Greenleaf, Lieut. JAMES M. TAULBEE, Lexington.

To Camp Meade, Annapolis Junction, Md., for duty, from Camp Meade, Lieut. MORTON M. MOSS, Bowling Green.

To Camp Shelby, Hattiesburg, Miss., for duty, from Camp Wheeler, Lieut. JOHN P. WHEELER, Carrollton.

To Camp Sheridan, Ala., for temporary duty, from Evans Dental Institute, Philadelphia, Lieut. FREDERICK L. KOONTZ, Louisville.

To Camp Sherman, Chillicothe, Ohio, for duty, from Fort Benjamin Harrison, Lieut. HENRY H. DUKE, Louisville.

To Camp Taylor, Louisville, Ky., as member of board for examination of command for tuberculosis, from Fort Benjamin Harrison, Lieut. EDWIN W. MONTGOMERY, Vince Grove.

To Fort Oglethorpe, for duty, from Camp Wheeler, Lieut. JOHN P. WHEELER, Carrollton.

To New York City, Neurological Institute, for intensive training in brain surgery, Lieuts. NATHAN B. [illegible], Philadelphia; from Camp Greenleaf, MARSHALL C. RUMBAUGH, Dorranceton.

To United States Army General Hospital No. 4, for duty with Hospital Unit "A," Lieut. WILLIAM C. POWELL, Bryn Mawr.

Honorably discharged on account of being physically disqualified for active service, Capt. JOHN C. DaCOSTA, Jr., Philadelphia.

Honorably discharged, Lieut. CHARLES S. ROTTNER, Philadelphia.

To his home and honorably discharged on account of being physically disqualified for active service, Capt. LAUREN C. THOMAS, Latrobe.

To the inactive list, from Camp Greenleaf, Lieut. SAMUEL McCLARY, Philadelphia.

Rhode Island

To Camp Dix, Wrightstown, N. J., for duty, from Fort Benjamin Harrison, Capt. THOMAS F. SCANLON, Providence.

To Camp Logan, base hospital, from Camp Beauregard, Capt. ROSWELL S. WILCOX, Providence.

To Camp Upton, Yaphank, L. I., N. Y., for examination of command for tuberculosis, from Walter Reed General Hospital, Lieut. NORMAN B. COLE, Newport.

To Morrison, Va., for duty, from Fort Benjamin Harrison, Lieut. BENJAMIN J. BUTLER, East Providence Center.

South Carolina

To Fort Logan H. Roots, Ark., for duty, from Gettysburg, Pa., Capt. LAWRENCE R. CRAIG, Dillon.

To Fort McPherson, Ga., for duty with Hospital Unit "O," from Camp Greene, Charlotte, N. C., Lieut. ROBERT H. CRAWFORD, Rock Hill.

South Dakota

To Fort Oglethorpe, Ga., for duty, from Fort Riley, Lieut. LINDSAY Z. FLETCHER, Montrose.

Tennessee

To Army Medical School, Washington, D. C., for duty in the bacteriologic laboratory, from Rockefeller Institute, Lieut. ANDREW B. JONES, Nashville.

To Camp Lee, Petersburg, Va., for temporary duty, from Philadelphia General Hospital, Lieut. HOWARD M. FRANCISCO, Nashville.

To Fort McPherson, Ga., for duty with Hospital Unit "S," Capt. ALBERT W. HARRIS, Nashville.

To Knoxville, Tenn., to report to the recruiting officer for duty, Lieut. REESE W. PATTERSON, Knoxville.

New Orleans, Charity Hospital, for instruction, and on completion to *Fort Worth, Texas*, base hospital, Lieut. PAUL H. FAUCETT, Columbia.

To New York City, Post-Graduate Hospital, for instruction in dermatology and urology, from Camp Lee, Lieut. BENJAMIN C. ARNOLD, Jackson.

Texas

To Camp Bowie, Fort Worth, Texas, base hospital, from Camp Greenleaf, Lieut. CALVIN W. DAVIS, Long View.

To Camp Kearney, Linda Vista, Calif., base hospital, Lieut. WILL M. SCHULTZ, Georgetown.

To Camp Meade, Annapolis Junction, Md., for temporary duty, from Evans Dental Institute, Philadelphia, Capt. JOSEPH E. JOHNSON, Kirvin.

To Camp Taylor, Louisville, Ky., base hospital, from Evans Dental Institute, Philadelphia, Major WILLIAM E. HALL, Texas City.

To Fort Riley, for duty with Evacuation Hospital No. 7, from Camp Grant, Lieut. GEORGE L. LANGWORTHY, Lakeview.

To Fort Sam Houston, for duty in the department laboratory, from Rockefeller Institute, Lieut. RICHARD C. CURTIS, Temple.

To Garden City, L. I., N. Y., for duty, from San Antonio, Texas, Lieut. DOUGLAS S. EDWARDS, San Antonio.

To Morrison, Va., for duty, from Richmond, Va., Lieut. HENRY F. WILKINS, Fort Worth.

To report by wire to the Commanding General, Southern Department, Lieut. CHARLES F. CLAYTON, Lubbock.

To report in person to the governor, Panama Canal, for assignment to duty, from Panama Canal Department, Lieut. PAUL J. CONNOR, Madisonville.

Utah

To Camp Gordon, Atlanta, Ga., as member of board for examination of command for tuberculosis, from Camp Greenleaf, Lieut. GEORGE E. McBRIDE, Magna.

Vermont

To Camp Greenleaf, Fort Oglethorpe, Ga., for instruction, Lieut. DENNIS J. SHEEHAN, Lyndonville.

To Camp Sherman, Chillicothe, Ohio, as member of board for examination of command for tuberculosis, from Fort Benjamin Harrison, Lieut. ROLLIN D. WORDEN, Montgomery Center.

Virginia

To Camp Lee, Petersburg, Va., for duty, Lieuts. OLIVER C. BRUNK, Richmond; JULIUS J. HULCHER, Richmond; GEORGE S. BURT, Roanoke; for duty in the base hospital, from Fort Benjamin Harrison, Lieut. JUNIUS E. WARINNER, Jr., Richmond.

To Camp Taylor, Louisville, Ky., base hospital, from Evans Dental Institute, Lieut. SAMUEL P. CAST, Portsmouth.

To Camp Upton, Yaphank, L. I., N. Y., for examination of command for tuberculosis, from Walter Reed General Hospital, Lieut. THOMAS N. DAVIS, Lynchburg.

To Fort Oglethorpe, for duty with Evacuation Hospital No. 3, from Camp Greenleaf, Lieut. WILLIAM L. BRENT, Colonial Beach.

To Fort Omaha, Neb., for duty, from Fort Benjamin Harrison, Lieut. GRANVILLE EASTHAM, Rapidan.

To Fort Riley, Kan., base hospital, from Fort Benjamin Harrison, Lieut. ROBERT J. STYER, Jetersville.

Washington

To Army Medical School, Washington, D. C., for duty in the bacteriologic laboratory, from Rockefeller Institute, Capt. AUSTIN U. SIMPSON, Seattle.

To Fort Des Moines, Iowa, from Camp Robinson, Sparta, Wis., Capt. IRA C. BROWN, Seattle.

To his home and honorably discharged on account of being physically disqualified for active service, from Camp Lewis, Lieut. CHARLES S. NOBLE, Seattle.

West Virginia

To Camp Lee, Petersburg, Va., as member of board for examination of command for tuberculosis, Lieut. DAVID P. SCOTT, Ashland.

Wisconsin

To Camp Custer, Battle Creek, Mich., as member of board for examination of command for tuberculosis, from Fort Benjamin Harrison, Lieut. IRVING A. MYERS, Cottage Grove.

To Camp Dodge, Des Moines, Iowa, for examination of command for tuberculosis, from Fort Benjamin Harrison, Lieut. CHARLES H. MEYST, Burlington.

To Camp Pike, Little Rock, Ark., for base hospital, from Fort Benjamin Harrison, Lieut. CHARLES B. RYDELL, Superior.

To Cleveland, Ohio, for instruction and on completion to *Camp McClellan*, base hospital, Lieut. GUSTAVE E. ECK, Lake Mills.

To Fort Logan H. Roots, Ark., base hospital, from Fort Benjamin Harrison, Lieut. LEO H. FLYNN, Eau Claire.

To Fort Oglethorpe, for duty, from Camp Meade, Capt. RALPH KAYSON, Plymouth.

To Fort Riley, Kan., for instruction, Capt. CHARLES A. CRITCHLOS, Mellen.

To New York City, for instruction, and on completion to *Rochester, Minn.*, for instruction, Lieut. THOMAS J. SNODGRASS, Janesville; to *Post-Graduate Medical School* for instruction in urology and dermatology, from Fort Ethan Allen, Lieut. ELIAS BIBBY, Milwaukee.

To Pittsburgh, Pa., for instruction in military roentgenology, Capt. GENTZ PERRY, Amery.

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest; such as relate to society activities, new hospitals, education, public health, etc.)

CALIFORNIA

Dinner to Base Hospital Staff.—At a banquet given at the Los Angeles Athletic Club, November 8, by 125 physicians of Los Angeles and vicinity, the guest of honor was Dr. Rea E. Smith, and sixteen other physicians of Los Angeles who make up the base unit for war service. Dr. Walter Lindley officiated as toastmaster.

Personal.—Dr. George A. Zorb, a member of the resident staff of the Receiving Hospital, Los Angeles, has been seriously ill from septicemia, due to an operation wound, but is now convalescent.——Dr. Clarence A. Wills, San Leandro, for many years superintendent of the Alameda County Infirmary, Oakley, has resigned to enter the military service.

CONNECTICUT

Personal.—The directors of the Gaylor Farm Sanitarium, New Haven, have voted a leave of absence for six months to the superintendent, Dr. David R. Lyman, who is going to France to study tuberculosis conditions.——Dr. J. E. Radding has been appointed assistant to Dr. James B. Dinnan, superintendent of the State Sanatorium, Meriden, succeeding Dr. Cole B. Gibson, who has entered military service.

Dietitians Organize.—The Connecticut Association for Dietitians has recently been organized. The object of the organization is to promote closer cooperation between dietary departments and allied departments. While the founders are hospital dietitians only, membership is open to all who have contributed to and are interested in the advancement of dietetics. It is thought that there is a great need of better trained dietitians, and that this can be accomplished by close work among physicians, hospital superintendents, heads of home economics departments and hospital dietitians. At the November meeting, held at Grace Hospital, New Haven, the following officers were elected: president, Miss E. M. Geraghty, New Haven; vice president, Miss Laura Siegel, Stamford, and secretary-treasurer, Miss Ethel C. Pipes, Hartford.

ILLINOIS

Personal.—Harold B. Fromme, Peoria, has been appointed quarantine officer by the state director of health, and detailed to duty at Camp Grant, Rockford, succeeding P. E. Cooney.

Health of Chicago.—November 24, fifty-four new cases of diphtheria and six deaths from this disease were reported to the health department. Infantile paralysis is rapidly disappearing. The health department is urging citizens to boil water, as recent severe storms have made the lake water of doubtful purity. Chlorination is being resorted to as a means of controlling the contamination.

Control of Venereal Diseases.—Rules for the control of venereal diseases in Illinois, including placarding of immoral houses, provided especially to protect troops quartered in the state were announced by Dr. C. St. Clair Drake, state director of health. The regulations include reports of all cases of venereal diseases and the placarding of all premises suspected of being used for immoral purposes, the provision of proper medical care for indigent infected persons, and the prohibiting of engaging in any occupation the nature of which is such that it may be borne to others of any person having active infectious venereal disease. Penalties of a fine up to $200 or imprisonment in jail, not to exceed six months, or both, are provided for violation of the regulations.

Antituberculosis Meeting.—At the ninth annual meeting of the Illinois Association for the Study and Prevention of Tuberculosis, held in Champaign, November 9, the following officers were elected: president, Dr. George Thomas Palmer, Springfield (reelected for the seventh term); vice presidents, Dr. William A. Evans, Chicago; Ethan Allen Gray, Chicago; Cecil M. Jack, Decatur, and Lewis C. Taylor, Springfield; secretary, Dr. Jeanette C. Wallace, Peoria; treasurer, Mr. David R. Forgan, Chicago; executive committee, new members: Dr. James W. Pettit, Chicago; Mrs. Joseph T. Mason, Aurora, and George W. Perkins, Chicago, and holdover members, Mrs. A. L. Adams, Jacksonville; Dr. Edward W. Fiegenbaum, Edwardsville, and Dr. Orville W. McMichael, Chicago.

INDIANA

District Meeting.—The annual meeting of the Seventh Indiana Councilor District Medical Association was held in Danville, November 21. Dr. Samuel E. Earp was elected president; Dr. Murray N. Hadley, secretary, and Dr. Thomas B. Eastman, councilor, all of Indianapolis.

Personal.—Drs. Eric A. Crull, Adam L. Schneider and Abraham J. Kesler, all of Fort Wayne, have been appointed members of the board of health of that city.——Dr. Benjamin F. Tetters, Middlebury, who was operated on recently, is reported to be making satisfactory progress toward recovery.

State Housing Laws.—The state board of health has issued orders to the city boards of health of Gary, Whiting, Hammond, East Chicago and Indiana Harbor that they take immediate steps to enforce the state housing laws. If the cities do not respond, the state board will take charge and enforce the laws in an effort to clean up the "gross insanitary conditions" in those cities.

New Isolation Hospital.—Plans have been submitted to the city board of health, Indianapolis, for a new contagious disease hospital to cost from $90,000 to $100,000. Investigation will start at once to see if money will be available for the construction of the building at this time. While the present facilities for the treatment of persons with contagious diseases are inadequate, it is not believed that the building can be constructed at this time, owing to the lack of funds.

IOWA

Hospital Unit Mobilizes.—Hospital Unit K, Council Bluffs, was mobilized at Fort Porter, N. Y., November 14, and is being equipped for service. This unit consists of twelve medical officers, one head nurse, twenty female nurses and fifty enlisted men. The medical personnel consists of the following reserve officers: Major Donald Macrae, Jr., director, Council Bluffs; Capts. F. Earl Bellinger, general surgery, Council Bluffs; John W. Shuman, chief medical officer, Sioux City; Louis L. Henninger, eye, ear, nose and throat, Council Bluffs, and Chalmers A. Hill, orthopedic surgery, Council Bluffs; Lieuts. John S. McAtee, genito-urinary surgery; Robert S. Moth, adjutant, medical, and Louis E. Hanisch, general surgery, Council Bluffs; Aldis A. Johnson, pathologist and bacteriologist, and George P. Pratt, medical, Omaha; Robert C. Crumpton, medical, Webster City, and Albert E. Sabin, medical, Kirkman.

Personal.—Lieut. Daniel J. McCarthy, M. R. C., U. S. Army, Davenport, who recently started for Roumania, has arrived safely in Moscow, Russia.——Dr. Emil O. Ficke, Davenport, formerly the county physician, has been appointed a member of the Board of Commissioners for the Insane of Scott County, to succeed Dr. John A. DeArmand, deceased.——Drs. James M. Fettes, William T. Shepard, G. Henry Mammen, William W. Larsen and Martin J. Joynt, all of LeMars, have united to form the LaMars Clinic, which will be located on the second floor of the Royal Building.——Dr. James B. Miner, Augustus F. Kober, Julius Niemack and Raymond W. Stober, all of Charles City, have been elected directors of the Cedar Valley Hospital, Charles City.——Dr. Mark F. Boyd, professor of preventive medicine and hygiene in the State University of Iowa, Iowa City, has accepted the position of head of the department of bacteriology in the University of Texas, Galveston.

MARYLAND

Personal.—Lieut. James M. Shields, formerly of Colorado, has been stationed at the base hospital at Fort McHenry, where he will have charge of the eye, ear, nose and throat ward.——Dr. Alexander R. Mitchell, Monkton, has been appointed health officer of the seventh district of Baltimore County.——Dr. James A. Nydegger, U. S. P. H. S., Baltimore, delivered an address on the "Relation of the Rural Schools to National Health," at the Maryland State Teachers' Association. Dr. Nydegger claims the insanitary condition of our rural schools is the chief cause of the poor physical condition of so many young men who have been drafted and found to be unfit for military service.——Dr. William S. Thayer, who has been in Petrograd for several months with the American Red Cross Mission, is on his way back to the United States.

Report of Lunacy Commission.—At the semiannual meeting of the State Lunacy Commission with the boards of managers of the State Institutions for the Insane and Feebleminded and the Board of State Aid and Charities, held, November 22, in Baltimore, the report of the commission showed that there were in the twenty institutions under the supervision of the commission, on Sept. 30, 1917, 5,196 patients, or one patient to every 262 of the population of Maryland. There were admitted during the biennial period, 4,557 patients. The total number of patients discharged and died during the biennial period was 4,194, leaving a net increase of 363 patients for the two years. During the past five years there has been an average yearly net increase of 150 patients. The report on the after-care work for the past year showed that a saving of $10,693 had been made by paroling patients under the supervision of the after-care agent and making them more or less self-supporting. In all 124 patients were paroled under the supervision of this department. As a result of a preliminary survey of the feebleminded, conducted through the cooperation of the Committee on the Prevention of the Feebleminded, it was recommended that a complete survey of this class of defectives be made throughout Maryland, during the coming year. The report urges that farm colonies be established at the state institutions to supply sufficient beds for the rapidly increasing number of insane and feebleminded at the lowest possible per capita, as well as to increase the farming activities of the institutions.

MISSOURI

Correction.—The statement in a recent issue that Dr. William A. Clark, Jefferson City, had been appointed physician to the penitentiary was erroneous. Dr. Clark is only acting as prison physician at the request of the board until the board can decide on a permanent appointment.

Free Syphilis Clinics.—The health department of St. Louis has completed plans for establishing free syphilis clinics under municipal control. All persons affected with syphilis in its infectious stage will be urged to go to the municipal clinic for treatment where at least two injections of salvarsan will be administered. An active campaign of education will be conducted to familiarize the people with the importance of these clinics and the benefits of early treatment of syphilis. It is the first instance of municipal clinics for syphilis to be established in this country.

Personal.—Dr. Alfred B. Miller, Macon, had a narrow escape from serious injury, when the front wheels of his automobile ran into an open gulley, the bridge having been broken down by a traction engine. He managed to stop his car on the brink, though the front wheels were extending over at least a foot.——Dr. Robert F. Hyland, St. Louis, suffered severe injuries on November 15, when his automobile collided with a motor truck.——Dr. Clarence A. McGuire, Kansas City, now on duty at a base hospital in France, has recovered from the injuries he suffered at the time Dr. Fitzsimmons was killed by a bomb dropped from a German aeroplane.

NEW YORK

Personal.—Dr. Joseph S. Lewis, Buffalo, suffered a fracture of the clavicle and other injuries in a collision between his automobile and a street car, November 14.——Dr. Edward Danforth, Bainbridge, who is in the military service in France, is reported to be ill.

Dinner Given Bissell.—The first health officers' class of the University of Buffalo gave a complimentary dinner to Dr. William G. Bissell, Buffalo, bacteriologist and chief of the bureau of laboratories of the Buffalo Department of Health and his assistants, at the Hotel Statler, November 21. Dr. Fowler A. Watters, Lockport, officiated as toastmaster, and addresses were delivered by Dr. Thomas H. McKee, dean of the University of Buffalo, on "The Attitude of the University of Buffalo Toward Health Officers and Their Work," and by Dr. William G. Bissell, on "The Need of a Closer Union Between Civil Laboratories and Rural Communities, and How to Obtain It." At the conclusion of this program, impromptu speeches were made.

New York City

Bellevue Hospital Unit Mobilizes.—The Base Hospital Unit of Bellevue Hospital has mobilized its 300 members at the Twelfth Regiment Armory. Among the personnel of the unit are thirty-five doctors and eighty-three nurses.

Reclamation Gymnasium.—Cornell University Medical College announces that it is about to establish a reclamation gymnasium in which classes will be conducted for men who have been rejected from the army and navy services on account of minor physical defects.

Flower Hospital Raises Flag.—Flower Hospital recently unfurled a service flag, carrying 120 stars, the gift of Major William Tod Helmuth and Mrs. Royal S. Copeland. As a part of the ceremony of presentation, 300 medical students in uniform paraded in the vicinity of the hospital.

Enforcement of Antispitting Law.—Health Commissioner Emerson has ordered police departments to enforce the antispitting law and to arrest all who spit in public places. In a letter to Chief Magistrate McAdoo he asks that the police magistrates act with determination in imposing suitable sentences on all such offenders.

The Hospital Intern Problem.—At a meeting of the Public Health Committee of the New York Academy of Medicine, regarding the hospital intern problem, the following resolution was adopted and endorsed by the president on behalf of the academy:

> *Resolved,* That the Public Health Committee of the New York Academy of Medicine suggest to the Surgeon-General of the United States Army the desirability of a change in the wording of the "Circular of Information on the Completion of Internships of Commissioned Officers (Form I-1)," permitting the period of internship to terminate in December of the year following graduation instead of in July of that year. Permission to remain on the inactive list for the period named should, of course, be granted only "if the exigencies of the service permit."

Personal.—Dr. Katherine B. Davis, who was recently appointed head of the New York Parole Board by Mayor Mitchell, has resigned to accept the general secretaryship of the Rockefeller Bureau of Social Hygiene.——Capt. Bertram DeN. Cruger, who is a member of the parole board, at present on leave of absence as a captain in charge of a depot brigade at Camp Upton, has been appointed to the position of head of the parole board for a term of ten years at a salary of $7,500 a year.——Dr. Theron J. Vosburgh has been appointed superintendent of the city farm at Warwick, which is conducted by the Board of Inebriety, to succeed Dr. Charles S. Stokes, who resigned a short time ago. The position carries a salary of $5,000.

Plan to Reduce the Number of Physically Unfit Sent to Camps.—Charles E. Hughes, chairman of the District Board of Appeals for New York, has appointed a committee of five physicians whose duties will be to try to find a way of reducing the number of physically unfit men sent to the National Army cantonments. The members of this committee are Drs. Ernest L. Hicks, George E. Doty, James E. Shuttleworth, Herman T. Radin and James S. Waterman, Brooklyn. The appointment of this committee was made at the suggestion of Dr. Robert L. Dickinson, Brooklyn, assistant chief of the Medical Committee on National Defense. It is said that from 2 to 9 per cent. of the men sent to the camps have been rejected after their arrival at the cantonments.

The Nursing Situation in New York.—The Standing Committee on Nursing of the Mayor's Committee of Women on National Defense has made a survey of the nursing situation in this city. Their census shows that there are in New York City 17,377 people engaged in some form of nursing service. Of this number 6,459 are graduate registered nurses and 3,849 are graduate nurses who are not registered. One in four of the registered nurses is enrolled with the Red Cross Nursing Service, making 1,701 Red Cross nurses who may be called on for war service. Probably 1,000 of these will be needed during the year. The pupil nurses who will be graduated during the year number 824; this leaves about 150 whose places will not be filled by new graduates. Several hospitals in order to meet the demand have taken larger classes than usual, Bellevue Hospital having initiated a plan of taking a certain number of pupil nurses who bear their own living expenses. Several hospitals are offering a shorter course to college women whom it is hoped will be qualified to take responsible positions in institutions and in the public health field. The report urges qualified young women to take up the profession of nursing in the training schools and prepare to fill the gaps in the nursing service that will be left open as the war goes on.

NORTH DAKOTA

Personal.—Dr. Charles H. Aylen, Drayton, left, November 14, for Winnipeg, to enter the Canadian Army Medical Corps.

Compulsory Vaccination.—North Dakota has had a compulsory vaccination law for several years, but it has never been enforced. Compulsory vaccination will be required in the schools of the state, this year, for the first time in its history. Reports to the state board of health, according to the *Bulletin* for October, indicate that at the present time, about 90 per cent. of the schools have observed the requirements.

OHIO

Sanatorium Completed.—The Fountain Park Sanitarium in Champaign County is now ready for occupancy. The building is three stories in height, erected at the approximate cost of $80,000.

Personal.—Dr. Abraham J. Shoemaker, Columbus, has resigned as night physician at the state penitentiary.——Dr. Sterling B. Taylor, Columbus, has assumed his duties as chief surgeon of the Toledo and Ohio Central and Zanesville and Western Railroads, with headquarters in Columbus.

Hospital Notes.—The old Schwartz Castle, Columbus, has been remodeled and opened as the Columbus Maternity Hospital. Dr. A. Livingston Stage is president of the corporation, which is not for profit. The hospital is open to all reputable physicians.——The effort adequately to care for charity patients at the hospitals of Marion was begun, October 20, by the city members of the Marion County Medical Society. By means of this organization all charity cases approved by the Marion Social Service League will be treated at the Marion General Hospital, or the Orchard Hospital. Dr. Auguste Rhu was selected as chief of staff, and Dr. Dana O. Weeks, secretary.

PENNSYLVANIA

Personal.—Dr. John L. Sagerson, Johnstown, who was painfully injured in an automobile accident, November 14, is reported to be doing well.——Lieut. G. Franklin Bell, M. R. C., U. S. Army, Williamsport, who has been ill at the cantonment camp, Greenville, S. C., is reported to be convalescent.

Medical Aid Society Elects.—At the annual meeting of the Aid Association of the Philadelphia County Medical Society, November 12, Dr. Samuel D. Risley was elected president, succeeding Dr. Jacob R. Shellenberger, relieved at his own request, and the following officers were reelected: vice president, Dr. Edward E. Montgomery; secretary, Dr. Lewis H. Adler, Jr.; treasurer, Dr. John B. Turner; consultant, Francis C. Adler, and directors, Dr. Isidor P. Strittmatter, William S. Wray and William T. Hamilton.

TEXAS

Changes in Regents' Board.—Dr. Ralph Steiner, Austin, has been appointed a member of the board of regents of the University of Texas, and Dr. S. J. Jones, Salado, has resigned as a member of the board.

The State Board and the State Journal.—An arrangement has been made by which the matter heretofore contained in the *Monthly Bulletin* of the Texas Board of Health will be printed in the *State Journal of Medicine*, which is owned by the state medical association. This is similar to the arrangement in Ohio. The separate bulletin of the department is to be discontinued.

Society Meeting.—At the annual meeting of the Fourth District Medical Society, held in Brownwood, November 10, Dr. Joseph E. Dildy, Lampasas, was elected president, and Dr. J. William Blasdell, Ballinger, secretary. Coleman was selected as the place of meeting for next year.——At the semiannual meeting of the South Texas District Medical Society, held in Beaumont, October 11, Dr. James E. Thompson, Galveston, was elected president; Dr. Wil T. Williams, Beaumont, vice president, and Dr. Albert H. Braden, Beaumont, secretary-treasurer. Houston was selected as the next place of meeting.

Bureau of Rural Sanitation.—The Texas State Board of Health has created a Bureau of Rural Sanitation whose activities will be devoted to directing, supervising and assisting in rural health work. Dr. Platt W. Covington, Marquez, has been placed at the head of the department. From $3,000 to $6,000 will be spent this year in intensive community health work in the rural districts of the counties agreeing to employ four local assistants at $50 a month each, for a period of four, eight or twelve months. These assistants are to work with a staff of trained sanitarians furnished by the state and the International Health Board, the state legislature having made an appropriation of $90,000 for joint work with the International Health Board for intensive measures against preventable diseases in the rural districts. The following counties have made appropriations, under the foregoing arrangements, to carry on this work: Harris, Dallas, McLennan, Bexar, Jefferson, San Jacinto, Polk, Leon, Hardin, Trinity and Wharton. The work is now in progress in Polk, Dallas and Harris counties.

CANADA

Personal.—Lieut.-Col. Walter T. Connell, C. A. M. C., has resigned as consulting physician to the Kingston (Ont.) Penitentiary, and has been succeeded by Dr. Robert Hanley, Kingston.——Lieut.-Col. Charles H. Gilmour, Toronto, now surgeon-in-chief of the Ontario Military Hospital, Orpington, England, has been made a member of the Royal College of Surgeons, London.

Hospital News.—Oshawa, Ont., is to have a maternity hospital, a donation of his residence, by Mr. R. S. McLaughlin of that town.——The Isolation Hospital at Saskatoon, Sask., has been completed. It is situated adjacent to the city hospital, comprises four wings and contains twelve wards, with additional accommodation for the nursing staff. Accommodation is also provided for insane patients pending their removal to a hospital for the insane; so it will be no longer necessary to place such patients in the common jail.——The Esquimalt Convalescent Hospital has lately been extended by the addition of a department of vocational training. The medical officer in charge is Dr. Edward S. Hasell, who was formerly on the surgical staff of the Royal Jubilee Hospital, Victoria, B. C.

University News.—In a recent speech Sir Robert Falconer, president of the University of Toronto, stated there were at present over 6,000 undergraduates of that university on active service overseas, 1,000 of whom were serving in the ranks. He considers that medical students should be exempt from conscription in Canada, and that the medical faculties of the universities in Canada should be formed into medical corps so as to be available if required for the treatment of returned soldiers.——Lieut.-Col. Hadley Williams, London, Ont., has returned from the Ontario Military Hospital, Orpington, England, and has resumed his duties as professor of surgery in the Western University, London, Ontario.——Dalhousie University, Halifax, N. S., has the largest registration in the first year class in medicine in its history. Most of the students of the higher years have returned, but many members of the teaching staff are still on active military service.——The total number of students registered in the medical faculty of McGill University, Montreal, is 362; in the first year there are ninety-three men, a larger number than last year. Fifth year students will be graduated on April 1, so as to permit of going overseas immediately thereafter.

GENERAL

Southern Medical Women Meet.—At the fifth annual meeting of the women physicians of the Southern Medical Association which was held in Memphis, November 13, the following officers were elected: president, Dr. M. Louise Strobel, Washington, D. C.; vice presidents, Drs. Elizabeth C. Kane, Memphis, Tenn., and Olive A. C. Wilson, Paragould, Ark., and secretary-treasurer, Dr. L. Rosa H. Gantt, Spartanburg, S. C.

Southern Railway Surgeons Elect Officers.—At the annual meeting of the Southern States Association of Railway Surgeons, held in connection with the meeting of the Southern Medical Association at Memphis, November 14, Dr. Inman W. Cooper, Meridian, Miss., was elected president; Dr. William A. Chapman, Cedartown, Ga., vice president, and Dr. Ambrose McCoy, Jackson, Tenn., secretary.

Southern Physicians Elect Officers.—At the eleventh annual meeting of the Southern Medical Association, held in Memphis, Tenn., November 12 to 15, the following officers were elected: president, Dr. Lewellys F. Barker, Baltimore; vice presidents, Drs. William H. Deaderick, Hot Springs, Ark., and Thomas C. Holloway, Hazard, Ky., and secretary, Dr. Seale Harris, Birmingham, Ala.; acting secretary, Dr. James R. Garber, Birmingham, Ala.; editor of the *Southern Medical Journal*, Dr. Marye Y. Dabney, Birmingham, Ala., and chairman of the executive council, Dr. Henry H. Martin, Savannah, Ga. Asheville, N. C., was selected as the place of meeting for 1918. On Sunday, the day before the opening of the convention, the pulpits of the city were filled by medical men.

FOREIGN

Deaths in the Profession Abroad.—Hugh McMinn Smellie, M.B., C.M., Edinburgh, 1886; Sanhead, Wigtownshire, Scotland; aged 60; surgeon on the Anchor Line steamships; surgeon of the *Cameronia*, when she was torpedoed and sunk in European waters; died suddenly on board the *Tuscania* in Erie Basin, Brooklyn, November 11, from heart disease.

PARIS LETTER

Paris, Nov. 1, 1917.

The War

APPENDICITIS IN THE ARMIES IN THE FIELD

At one of the recent meetings of the Société de chirurgie de Paris, Dr. Walther, assistant professor on the Faculté de médecine de Paris, and surgeon of the hospitals, presented a memoir on this subject by Dr. Rouhier. Rouhier has been astonished at the unusual number of cases of appendicitis occurring in the armies in the field; appendicitis occurs more frequently here than among civilians of the same age. This may be explained by the conditions of life at the front: the meat diet, the free use of wine, fatigue, and exposure to wet and cold, all of which may awaken an old chronic appendicitis, and convert it into an acute case of more or less severity. These conditions may even give rise to acute intestinal affections and appendicitis, which is apparently primary. Rouhier has also been struck by the particular gravity of the attacks he has observed, perhaps the result of overexertion, which lowers the resistance to the infection. Walther does not agree with Rouhier that irregular forms of appendicitis in which the diagnosis is dubious are more frequent at the front than at the rear; perhaps they are more often overlooked on account of the difficulty of examination. On the other hand, Walther agrees with him that as soon as the diagnosis of appendicitis is made, the patient should be evacuated without delay and without relay, as would be a patient with an abdominal wound, to the surgical formation where he can be taken care of properly: operated on, if possible, and treated expectantly if the circumstances permit. Rouhier, discussing the question of immediate operation as against expectant treatment, is of the opinion that at the front, more than at the rear, intervention is indicated; but Walther declares that operation is urgently indicated in both situations alike.

Rouhier has also studied the connection between appendicitis and typhoid fever, which, he believes, predisposes to appendicitis later. One must bear in mind that frequently it is difficult to diagnosticate between appendicitis, periappendicitis and peri-ileotyphlitis in relation to the habitual seat of typhoid ulcerations in Peyer's patches. In closing, Rouhier mentioned a special and particularly grave form of appendicitis, that is, perforating appendicitis, occurring as the primary manifestation of typhoid fever. In one instance, within twenty-four hours the appendix became gangrenous and perforated, with a discharge of seropurulent fluid into the abdominal cavity. This was the first manifestation of the typhoid fever, which progressed steadily and finally terminated in the death of the patient in about a month.

USE OF MORPHIN BEFORE OPERATIONS AND FOR THE WOUNDED

At a recent session of the Society of Comparative Pathology, Dr. Regnault discussed the use of morphin in the wounded. Morphin is used, first, as an adjuvant to anesthesia, and, second, to dull the pains of the wounded, aside from operations. In the first case, one must make certain reservations as to that method of procedure, as it superposes two intoxications; however, that method has given good results under varying circumstances. Although of little value when given with chloroform and ethyl chlorid, there appears to be some advantage in restraining the shock which occurs during operations on large nerve trunks, when one cannot resort to Crile's method of double anesthesia, blocking the principal nerve trunks by the local injection of stovain, novocain, etc. The use of a small dose of morphin cannot be compared to the chronic intoxication which follows the habitual use of anodynes. When local anesthesia is resorted to, 0.5 to 1 cg. of morphin, administered before the operation is begun, has yielded excellent results. The same is true of a mixture of scopolamin and morphin. The efficacy of these drugs may be increased by resorting to psychotherapy. Besides making use of morphin at operations, Regnault also gives it to relieve the pain of the wounded, especially when the kidneys and brain are intact. The toxic action of small doses of morphin is less dangerous than the shock resulting from the pain and the fatigue following sleeplessness due to pain. Pain is an antidote to morphin; a small dose of morphin acts as a general stimulant, and not as an anodyne, as do the larger doses.

Colonel Le Bel Receives the Decoration of the Legion of Honor
